1.3 Introduction 3

1.3 Introduction

WCSLIB is a C library, supplied with a full set of Fortran wrappers, that implements the "World Coordinate System" (WCS) standard in FITS (Flexible Image Transport System). It also includes a PGPLOT-based routine, PGSBOX, for drawing general curvilinear coordinate graticules, and also a number of utility programs.

The FITS data format is widely used within the international astronomical community, from the radio to gamma-ray regimes, for data interchange and archive, and also increasingly as an online format. It is described in

• "Definition of The Flexible Image Transport System (FITS)", FITS Standard, Version 3.0, 2008 July 10.

available from the FITS Support Office at http://fits.gsfc.nasa.gov.

The FITS WCS standard is described in

- "Representations of world coordinates in FITS" (Paper I), Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061-1075
- "Representations of celestial coordinates in FITS" (Paper II), Calabretta, M.R., & Greisen, E.W. 2002, A&A, 395, 1077-1122
- "Representations of spectral coordinates in FITS" (Paper III), Greisen, E.W., Calabretta, M.R., Valdes, F.G., & Allen, S.L. 2006, A&A, 446, 747
- "Representations of distortions in FITS world coordinate systems", Calabretta, M.R. et al. (WCS Paper IV, draft dated 2004/04/22), available from http://www.atnf.csiro.au/people/Mark.← Calabretta
- "Mapping on the HEALPix Grid" (HPX, Paper V), Calabretta, M.R., & Roukema, B.F. 2007, MNRAS, 381, 865
- "Representing the 'Butterfly' Projection in FITS: Projection Code XPH" (XPH, Paper VI), Calabretta, M.R., & Lowe, S.R. 2013, PASA, 30, e050
- "Representations of time coordinates in FITS: Time and relative dimension in space" (Paper VII), Rots, A.H., Bunclark, P.S., Calabretta, M.R., Allen, S.L., Manchester R.N., & Thompson, W.T. 2015, A&A, 574, A36

Reprints of all published papers may be obtained from NASA's Astrophysics Data System (ADS), http-://adsabs.harvard.edu/. Reprints of Papers I, II (including HPX & XPH), and III are available from http://www.atnf.csiro.au/people/Mark.Calabretta. This site also includes errata and supplementary material for Papers I, II and III.

Additional information on all aspects of FITS and its various software implementations may be found at the FITS Support Office http://fits.gsfc.nasa.gov.

1.4 FITS-WCS and related software

Several implementations of the FITS WCS standards are available:

• The WCSLIB software distribution (i.e. this library) may be obtained from http://www.atnf.← csiro.au/people/Mark.Calabretta/WCS/. The remainder of this manual describes its use.

WCSLIB is included in the Astrophysics Source Code Library (ASCL https://ascl.net) as record ascl:1108.003 (https://ascl.net/1108.003), and in the Astrophysics Data System (ADS https://ui.adsabs.harvard.edu) with bibcode 2011ascl.soft08003C (https://ui.← adsabs.harvard.edu/abs/2011ascl.soft08003C).

• wcstools, developed by Jessica Mink, may be obtained from http://tdc-www.harvard.← edu/software/wcstools/.

```
ASCL: https://ascl.net/1109.015
ADS: https://ui.adsabs.harvard.edu/abs/2011ascl.soft09015M
```

• AST, developed by David Berry within the U.K. Starlink project, http://www.starlink.epac.uk/ast/ and now supported by JAC, Hawaii http://starlink.jach.hawaii.epac/ edu/starlink/. A useful utility for experimenting with FITS WCS descriptions (similar to wcsgrid) is also provided; go to the above site and then look at the section entitled "FITS-WCS Plotting Demo".

```
ASCL: https://ascl.net/1404.016
ADS: https://ui.adsabs.harvard.edu/abs/2014ascl.soft04016B
```

• SolarSoft, http://sohowww.nascom.nasa.gov/solarsoft/, primarily an IDL-based system for analysis of Solar physics data, contains a module written by Bill Thompson oriented towards Solar coordinate systems, including spectral, http://sohowww.nascom.nasa.⇔ gov/solarsoft/gen/idl/wcs/.

```
ASCL: https://ascl.net/1208.013
ADS: https://ui.adsabs.harvard.edu/abs/2012ascl.soft08013F
```

• The IDL Astronomy Library, http://idlastro.gsfc.nasa.gov/, contains an independent implementation of FITS-WCS in IDL by Rick Balsano, Wayne Landsman and others. See http←://idlastro.gsfc.nasa.gov/contents.html#C5.

Python wrappers to WCSLIB are provided by

• The **Kapteyn Package** http://www.astro.rug.nl/software/kapteyn/ by Hans Terlouw and Martin Vogelaar.

```
ASCL: https://ascl.net/1611.010
ADS: https://ui.adsabs.harvard.edu/abs/2016ascl.soft11010T
```

• pywcs, http://stsdas.stsci.edu/astrolib/pywcs/ by Michael Droettboom, which is distributed within Astropy, https://www.astropy.org.

```
ASCL (Astropy): https://ascl.net/1304.002
ADS (Astropy): https://ui.adsabs.harvard.edu/abs/2013ascl.soft04002G
```

Java is supported via

• CADC/CCDA Java Native Interface (JNI) bindings to WCSLIB 4.2 http://www.cadc-ccda. ← hia-iha.nrc-cnrc.gc.ca/cadc/source/ by Patrick Dowler.

and Javascript by

• wcsjs, https://github.com/astrojs/wcsjs, a port created by Amit Kapadia using Emscripten, an LLVM to Javascript compiler. wcsjs provides a code base for running WCSLIB on web browsers.

Julia wrappers (https://en.wikipedia.org/wiki/Julia_(programming_language)) are provided by

• WCS.jl, https://github.com/JuliaAstro/WCS.jl, a component of Julia Astro, https↔ ://github.com/JuliaAstro.

An interface for the R programming language (https://en.wikipedia.org/wiki/R_(programming← _language)) is available at

• Rwcs, https://github.com/asgr/Rwcs/by Aaron Robotham.

Recommended WCS-aware FITS image viewers:

```
    Bill Joye's DS9, http://hea-www.harvard.edu/RD/ds9/, and ASCL: https://ascl.net/0003.002
        ADS: https://ui.adsabs.harvard.edu/abs/2000ascl.soft03002S
    Fv by Pan Chai, http://heasarc.gsfc.nasa.gov/ftools/fv/.
        ASCL: https://ascl.net/1205.005
        ADS: https://ui.adsabs.harvard.edu/abs/2012ascl.soft05005P
```

both handle 2-D images.

Currently (2013/01/29) I know of no image viewers that handle 1-D spectra properly nor multi-dimensional data, not even multi-dimensional data with only two non-degenerate image axes (please inform me if you know otherwise).

Pre-built WCSLIB packages are available, generally a little behind the main release (this list will probably be stale by the time you read it, best do a web search):

- archlinux (tgz), https://www.archlinux.org/packages/extra/i686/wcslib.
- Debian (deb), http://packages.debian.org/search?keywords=wcslib.
- Fedora (RPM), https://admin.fedoraproject.org/pkgdb/package/wcslib.
- Fresh Ports (RPM), http://www.freshports.org/astro/wcslib.
- Gentoo, http://packages.gentoo.org/package/sci-astronomy/wcslib.
- Homebrew (MacOSX), https://github.com/Homebrew/homebrew-science.
- RPM (general) http://rpmfind.net/linux/rpm2html/search.php?query=wcslib, http://www.rpmseek.com/rpm-pl/wcslib.html.
- Ubuntu (deb), https://launchpad.net/ubuntu/+source/wcslib.

Bill Pence's general FITS IO library, **CFITSIO** is available from $http://heasarc.gsfc.nasa. \leftarrow gov/fitsio/$. It is used optionally by some of the high-level WCSLIB test programs and is required by two of the utility programs.

```
ASCL: https://ascl.net/1010.001
ADS: https://ui.adsabs.harvard.edu/abs/2010ascl.soft10001P
```

PGPLOT, Tim Pearson's Fortran plotting package on which PGSBOX is based, also used by some of the WCSLIB self-test suite and a utility program, is available from $http://astro.caltech.edu/\sim tjp/pgplot/$.

```
ASCL: https://ascl.net/1103.002
ADS: https://ui.adsabs.harvard.edu/abs/2011ascl.soft03002P
```

1.5 Overview of WCSLIB

WCSLIB is documented in the prologues of its header files which provide a detailed description of the purpose of each function and its interface (this material is, of course, used to generate the doxygen manual). Here we explain how the library as a whole is structured. We will normally refer to WCSLIB 'routines', meaning C functions or Fortran 'subroutines', though the latter are actually wrappers implemented in C.

WCSLIB is layered software, each layer depends only on those beneath; understanding WCSLIB first means understanding its stratigraphy. There are essentially three levels, though some intermediate levels exist within these:

- The **top layer** consists of routines that provide the connection between FITS files and the high-level WCSLIB data structures, the main function being to parse a FITS header, extract WCS information, and copy it into a wcsprm struct. The lexical parsers among these are implemented as Flex descriptions (source files with .I suffix) and the C code generated from these by Flex is included in the source distribution.
 - wcshdr.h,c Routines for constructing wcsprm data structures from information in a FITS header and conversely for writing a wcsprm struct out as a FITS header.
 - wcspih.l Flex implementation of wcspih(), a lexical parser for WCS "keyrecords" in an image header.
 A keyrecord (formerly called "card image") consists of a keyword, its value the keyvalue and an optional comment, the keycomment.
 - wcsbth.l Flex implementation of wcsbth() which parses binary table image array and pixel list headers
 in addition to image array headers.
 - getwcstab.h,c Implementation of a -TAB binary table reader in CFITSIO.

A generic FITS header parser is also provided to handle non-WCS keyrecords that are ignored by wcspih():

- fitshdr.h,I - Generic FITS header parser (not WCS-specific).

The philosophy adopted for dealing with non-standard WCS usage is to translate it at this level so that the middle- and low-level routines need only deal with standard constructs:

- wcsfix.h,c Translator for non-standard FITS WCS constructs (uses wcsutrne()).
- wcsutrn.l Lexical translator for non-standard units specifications.

As a concrete example, within this layer the CTYPEia keyvalues would be extracted from a FITS header and copied into the *ctype*[] array within a wcsprm struct. None of the header keyrecords are interpreted.

- The middle layer analyses the WCS information obtained from the FITS header by the top-level routines, identifying the separate steps of the WCS algorithm chain for each of the coordinate axes in the image. It constructs the various data structures on which the low-level routines are based and invokes them in the correct sequence. Thus the wcsprm struct is essentially the glue that binds together the low-level routines into a complete coordinate description.
 - wcs.h,c Driver routines for the low-level routines.
 - wcsunits.h,c Unit conversions (uses wcsulexe()).
 - wcsulex.l Lexical parser for units specifications.

To continue the above example, within this layer the *ctype*[] keyvalues in a wcsprm struct are analysed to determine the nature of the coordinate axes in the image.

Applications programmers who use the top- and middle-level routines generally need know nothing about
the low-level routines. These are essentially mathematical in nature and largely independent of FITS itself.
The mathematical formulae and algorithms cited in the WCS Papers, for example the spherical projection
equations of Paper II and the lookup-table methods of Paper III, are implemented by the routines in this layer,
some of which serve to aggregate others:

- cel.h,c Celestial coordinate transformations, combines prj.h,c and sph.h,c.
- spc.h,c Spectral coordinate transformations, combines transformations from spx.h,c.

The remainder of the routines in this level are independent of everything other than the grass-roots mathematical functions:

- lin.h,c Linear transformation matrix.
- dis.h,c Distortion functions.
- log.h,c Logarithmic coordinates.
- prj.h,c Spherical projection equations.
- sph.h,c Spherical coordinate transformations.
- spx.h,c Basic spectral transformations.
- tab.h,c Coordinate lookup tables.

As the routines within this layer are quite generic, some, principally the implementation of the spherical projection equations, have been used in other packages (AST, wcstools) that provide their own implementations of the functionality of the top and middle-level routines.

• At the grass-roots level there are a number of mathematical and utility routines.

When dealing with celestial coordinate systems it is often desirable to use an angular measure that provides an exact representation of the latitude of the north or south pole. The WCSLIB routines use the following trigonometric functions that take or return angles in degrees:

```
cosd(), sind(), sincosd(), tand(), acosd(), asind(), atand(), atan2d()
```

These "trigd" routines are expected to handle angles that are a multiple of 90° returning an exact result. Some C implementations provide these as part of a system library and in such cases it may (or may not!) be preferable to use them. wcstrig.c provides wrappers on the standard trig functions based on radian measure, adding tests for multiples of 90° .

However, wcstrig.h also provides the choice of using preprocessor macro implementations of the trigd functions that don't test for multiples of 90° (compile with <code>-DWCSTRIG_MACRO</code>). These are typically 20% faster but may lead to problems near the poles.

- wcsmath.h Defines mathematical and other constants.
- wcstrig.h,c Various implementations of trigd functions.
- wcsutil.h,c Simple utility functions for string manipulation, etc. used by WCSLIB.

Complementary to the C library, a set of wrappers are provided that allow all WCSLIB C functions to be called by Fortran programs, see below.

Plotting of coordinate graticules is one of the more important requirements of a world coordinate system. WCSLIB provides a PGPLOT-based subroutine, PGSBOX (Fortran), which handles general curvilinear coordinates via a user-supplied function - PGWCSL provides the interface to WCSLIB. A C wrapper, *cpgsbox()*, is also provided, see below.

Several utility programs are distributed with WCSLIB:

- wcsgrid extracts the WCS keywords for an image from the specified FITS file and uses cpgsbox() to plot a 2-D coordinate graticule for it. It requires WCSLIB, PGSBOX and CFITSIO.
- wcsware extracts the WCS keywords for an image from the specified FITS file and constructs wcsprm structs
 for each coordinate representation found. The structs may then be printed or used to transform pixel coordinates to world coordinates. It requires WCSLIB and CFITSIO.

- *HPXcvt* reorganises HEALPix data into a 2-D FITS image with HPX coordinate system. The input data may be stored in a FITS file as a primary image or image extension, or as a binary table extension. Both NESTED and RING pixel indices are supported. It uses CFITSIO.
- fitshdr lists headers from a FITS file specified on the command line, or else on stdin, printing them as 80-character keyrecords without trailing blanks. It is independent of WCSLIB.

1.6 WCSLIB data structures

The WCSLIB routines are based on data structures specific to them: wcsprm for the wcs.h,c routines, celprm for cel.h,c, and likewise spcprm, linprm, prjprm, tabprm, and disprm, with struct definitions contained in the corresponding header files: wcs.h, cel.h, etc. The structs store the parameters that define a coordinate transformation and also intermediate values derived from those parameters. As a high-level object, the wcsprm struct contains linprm, tabprm, spcprm, and celprm structs, and in turn the linprm struct contains disprm structs, and the celprm struct contains a prjprm struct. Hence the wcsprm struct contains everything needed for a complete coordinate description.

Applications programmers who use the top- and middle-level routines generally only need to pass wcsprm structs from one routine that fills them to another that uses them. However, since these structs are fundamental to WCSLIB it is worthwhile knowing something about the way they work.

Three basic operations apply to all WCSLIB structs:

- Initialize. Each struct has a specific initialization routine, e.g. wcsinit(), celini(), spcini(), etc. These allocate memory (if required) and set all struct members to default values.
- Fill in the required values. Each struct has members whose values must be provided. For example, for wcsprm these values correspond to FITS WCS header keyvalues as are provided by the top-level header parsing routine, wcspih().
- Compute intermediate values. Specific setup routines, e.g. wcsset(), celset(), spcset(), etc., compute intermediate values from the values provided. In particular, wcsset() analyses the FITS WCS keyvalues provided, fills the required values in the lower-level structs contained in wcsprm, and invokes the setup routine for each of them.

Each struct contains a *flag* member that records its setup state. This is cleared by the initialization routine and checked by the routines that use the struct; they will invoke the setup routine automatically if necessary, hence it need not be invoked specifically by the application programmer. However, if any of the required values in a struct are changed then either the setup routine must be invoked on it, or else the *flag* must be zeroed to signal that the struct needs to be reset.

The initialization routine may be invoked repeatedly on a struct if it is desired to reuse it. However, the *flag* member of structs that contain allocated memory (wcsprm, linprm, tabprm, and disprm) must be set to -1 before the first initialization to initialize memory management, but not subsequently or else memory leaks will result.

Each struct has one or more service routines: to do deep copies from one to another, to print its contents, and to free allocated memory. Refer to the header files for a detailed description.

1.7 Memory management

The initialization routines for certain of the WCSLIB data structures allocate memory for some of their members:

- wcsinit() optionally allocates memory for the *crpix*, *pc*, *cdelt*, *crval*, *cunit*, *ctype*, *pv*, *ps*, *cd*, *crota*, *colax*, *cname*, *crder*, and *csyer* arrays in the wcsprm struct (using lininit() for certain of these). Note that wcsinit() does not allocate memory for the *tab* array refer to the usage notes for wcstab() in wcshdr.h. If the *pc* matrix is not unity, wcsset() (via linset()) also allocates memory for the *piximg* and *imgpix* arrays.
- lininit(): optionally allocates memory for the *crpix*, *pc*, and *cdelt* arrays in the linprm struct. If the *pc* matrix is not unity, linset() also allocates memory for the *piximg* and *imgpix* arrays. Typically these would be used by wcsinit() and wcsset().
- tabini(): optionally allocates memory for the *K*, *map*, *crval*, *index*, and *coord* arrays (including the arrays referenced by *index*[]) in the tabprm struct. tabmem() takes control of any of these arrays that may have been allocated by the user, specifically in that tabfree() will then free it. tabset() also allocates memory for the *sense*, *p0*, *delta* and *extrema* arrays.
- disinit(): optionally allocates memory for the *dtype*, *dp*, and *maxdis* arrays. disset() also allocates memory for a number of arrays that hold distortion parmeters and intermediate values: *axmap*, *Nhat*, *offset*, *scale*, *iparm*, and *dparm*, and also several private work arrays: *disp2x*, *disx2p*, and *tmpmem*.

The caller may load data into these arrays but must not modify the struct members (i.e. the pointers) themselves or else memory leaks will result.

wcsinit() maintains a record of memory it has allocated and this is used by wcsfree() which wcsinit() uses to free any memory that it may have allocated on a previous invokation. Thus it is not necessary for the caller to invoke wcsfree() separately if wcsinit() is invoked repeatedly on the same wcsprm struct. Likewise, wcsset() deallocates memory that it may have allocated on a previous invokation. The same comments apply to lininit(), linfree(), and linset(), to tabini(), tabfree(), and tabset(), and to disinit(), disfree() and disset().

A memory leak will result if a wcsprm, linprm, tabprm, or disprm struct goes out of scope before the memory has been *free'd*, either by the relevant routine, wcsfree(), linfree(), tabfree(), or disfree() or otherwise. Likewise, if one of these structs itself has been *malloc'd* and the allocated memory is not *free'd* when the memory for the struct is *free'd*. A leak may also arise if the caller interferes with the array pointers in the "private" part of these structs.

Beware of making a shallow copy of a wcsprm, linprm, tabprm, or disprm struct by assignment; any changes made to allocated memory in one would be reflected in the other, and if the memory allocated for one was *free'd* the other would reference unallocated memory. Use the relevant routine instead to make a deep copy: wcssub(), lincpy(), tabcpy(), or discpy().

1.8 Diagnostic output

All WCSLIB functions return a status value, each of which is associated with a fixed error message which may be used for diagnostic output. For example

```
int status;
struct wcsprm wcs;
...

if ((status = wcsset(&wcs)) {
   fprintf(stderr, "ERROR %d from wcsset(): %s.\n", status, wcs_errmsg[status]);
   return status;
}
```

This might produce output like

```
ERROR 5 from wcsset(): Invalid parameter value.
```

The error messages are provided as global variables with names of the form *cel_errmsg*, *prj_errmsg*, etc. by including the relevant header file.

As of version 4.8, courtesy of Michael Droettboom (pywcs), WCSLIB has a second error messaging system which provides more detailed information about errors, including the function, source file, and line number where the error occurred. For example,

```
struct wcsprm wcs;

/* Enable wcserr and send messages to stderr. */
wcserr_enable(1);
wcsprintf_set(stderr);
...

if (wcsset(&wcs) {
   wcsperr(&wcs);
   return wcs.err->status;
}
```

In this example, if an error was generated in one of the prjset() functions, wcsperr() would print an error traceback starting with wcsset(), then celset(), and finally the particular projection-setting function that generated the error. For each of them it would print the status return value, function name, source file, line number, and an error message which may be more specific and informative than the general error messages reported in the first example. For example, in response to a deliberately generated error, the twos test program, which tests wcserr among other things, produces a traceback similar to this:

```
ERROR 5 in wcsset() at line 1564 of file wcs.c:
   Invalid parameter value.
ERROR 2 in celset() at line 196 of file cel.c:
   Invalid projection parameters.
ERROR 2 in bonset() at line 5727 of file prj.c:
   Invalid parameters for Bonne's projection.
```

Each of the structs in WCSLIB includes a pointer, called *err*, to a wcserr struct. When an error occurs, a struct is allocated and error information stored in it. The wcserr pointers and the memory allocated for them are managed by the routines that manage the various structs such as wcsinit() and wcsfree().

wcserr messaging is an opt-in system enabled via wcserr_enable(), as in the example above. If enabled, when an error occurs it is the user's responsibility to free the memory allocated for the error message using wcsfree(), celfree(), prjfree(), etc. Failure to do so before the struct goes out of scope will result in memory leaks (if execution continues beyond the error).

1.9 Vector API

WCSLIB's API is vector-oriented. At the least, this allows the function call overhead to be amortised by spreading it over multiple coordinate transformations. However, vector computations may provide an opportunity for caching intermediate calculations and this can produce much more significant efficiencies. For example, many of the spherical projection equations are partially or fully separable in the mathematical sense, i.e. $(x,y)=f(\phi)g(\theta)$, so if θ was invariant for a set of coordinate transformations then $g(\theta)$ would only need to be computed once. Depending on the circumstances, this may well lead to speedups of a factor of two or more.

WCSLIB has two different categories of vector API:

1.9 Vector API

Certain steps in the WCS algorithm chain operate on coordinate vectors as a whole rather than particular elements of it. For example, the linear transformation takes one or more pixel coordinate vectors, multiples by the transformation matrix, and returns whole intermediate world coordinate vectors.
 The routines that implement these steps, wcsp2s(), wcss2p(), linp2x(), linx2p(), tabx2s(), tabs2x(), disp2x() and disx2p() accept and return two-dimensional arrays, i.e. a number of coordinate vectors. Because WC-SLIB permits these arrays to contain unused elements, three parameters are needed to describe them:

- naxis: the number of coordinate elements, as per the FITS NAXIS or WCSAXES keyvalues,
- ncoord: the number of coordinate vectors.
- nelem: the total number of elements in each vector, unused as well as used. Clearly, nelem must equal or exceed naxis. (Note that when ncoord is unity, nelem is irrelevant and so is ignored. It may be set to 0.)

ncoord and *nelem* are specified as function arguments while *naxis* is provided as a member of the wcsprm (or linprm or disprm) struct.

For example, wcss2p() accepts an array of world coordinate vectors, world[ncoord][nelem]. In the following example, naxis = 4, ncoord = 5, and nelem = 7:

```
s1
    x1
        у1
            t1
                u
s2
    x2
        y2
            t2
                u
                    u
                        u
53
   x3
        yЗ
           t3
                u
                    u
                        u
s4
   x4
        у4
            t4
s 5
   x5
        v5
            t5
```

where *u* indicates unused array elements, and the array is laid out in memory as

```
s1 x1 y1 t1 u u u s2 x2 y2 ...
```

Note that the *stat[]* vector returned by routines in this category is of length *ncoord*, as are the intermediate *phi[]* and *theta[]* vectors returned by wcsp2s() and wcss2p().

Note also that the function prototypes for routines in this category have to declare these two-dimensional arrays as one-dimensional vectors in order to avoid warnings from the C compiler about declaration of "incomplete types". This was considered preferable to declaring them as simple pointers-to-double which gives no indication that storage is associated with them.

Other steps in the WCS algorithm chain typically operate only on a part of the coordinate vector. For example, a spectral transformation operates on only one element of an intermediate world coordinate that may also contain celestial coordinate elements. In the above example, spcx2s() might operate only on the s (spectral) coordinate elements.

Routines like spcx2s() and celx2s() that implement these steps accept and return one-dimensional vectors in which the coordinate element of interest is specified via a starting address, a length, and a stride. To continue the previous example, the starting address for the spectral elements is s1, the length is 5, and the stride is 7.

1.9.1 Vector lengths

Routines such as spcx2s() and celx2s() accept and return either one coordinate vector, or a pair of coordinate vectors (one-dimensional C arrays). As explained above, the coordinate elements of interest are usually embedded in a two-dimensional array and must be selected by specifying a starting point, length and stride through the array. For routines such as spcx2s() that operate on a single element of each coordinate vector these parameters have a straightforward interpretation.

However, for routines such as celx2s() that operate on a pair of elements in each coordinate vector, WCSLIB allows these parameters to be specified independently for each input vector, thereby providing a much more general interpretation than strictly needed to traverse an array.

This is best described by illustration. The following diagram describes the situation for cels2x(), as a specific example, with nlng = 5, and nlat = 3:

```
lng[0] lng[1] lng[2] lng[3] lng[4]
----- -----
lat[0] | x,y[0] x,y[1] x,y[2] x,y[3] x,y[4]
lat[1] | x,y[5] x,y[6] x,y[7] x,y[8] x,y[9]
lat[2] | x,y[10] x,y[11] x,y[12] x,y[13] x,y[14]
```

In this case, while only 5 longitude elements and 3 latitude elements are specified, the world-to-pixel routine would calculate nlng * nlat = 15 (x,y) coordinate pairs. It is the responsibility of the caller to ensure that sufficient space has been allocated in **all** of the output arrays, in this case phi[], theta[], theta[], theta[], theta[], theta[].

Vector computation will often be required where neither lng nor lat is constant. This is accomplished by setting nlat = 0 which is interpreted to mean nlat = nlng but only the matrix diagonal is to be computed. Thus, for nlng = 3 and nlat = 0 only three (x,y) coordinate pairs are computed:

```
lng[0] lng[1] lng[2] ----- lat[0] | x,y[0] lat[1] | x,y[1] lat[2] | x,y[2]
```

Note how this differs from nlng = 3, nlat = 1:

```
lng[0] lng[1] lng[2] ----- ----- lat[0] | x,y[0] x,y[1] x,y[2]
```

The situation for celx2s() is similar; the x-coordinate (like *lng*) varies fastest.

Similar comments can be made for all routines that accept arguments specifying vector length(s) and stride(s). (tabx2s() and tabs2x() do not fall into this category because the -TAB algorithm is fully *N*-dimensional so there is no way to know in advance how many coordinate elements may be involved.)

The reason that WCSLIB allows this generality is related to the aforementioned opportunities that vector computations may provide for caching intermediate calculations and the significant efficiencies that can result. The high-level routines, wcsp2s() and wcss2p(), look for opportunities to collapse a set of coordinate transformations where one of the coordinate elements is invariant, and the low-level routines take advantage of such to cache intermediate calculations.

1.9.2 Vector strides

As explained above, the vector stride arguments allow the caller to specify that successive elements of a vector are not contiguous in memory. This applies equally to vectors given to, or returned from a function.

As a further example consider the following two arrangements in memory of the elements of four (x,y) coordinate pairs together with an s coordinate element (e.g. spectral):

```
    x1 x2 x3 x4 y1 y2 y3 y4 s1 s2 s3 s4
        the address of x[] is x1, its stride is 1, and length 4,
        the address of y[] is y1, its stride is 1, and length 4,
        the address of s[] is s1, its stride is 1, and length 4.
```

```
    x1 y1 s1 x2 y2 s2 x3 y3 s3 x4 y4 s4
    the address of x[] is x1, its stride is 3, and length 4, the address of y[] is y1, its stride is 3, and length 4, the address of s[] is s1, its stride is 3, and length 4.
```

For routines such as cels2x(), each of the pair of input vectors is assumed to have the same stride. Each of the output vectors also has the same stride, though it may differ from the input stride. For example, for cels2x() the input lng[] and lat[] vectors each have vector stride sll, while the x[] and y[] output vectors have stride sxy. However, the intermediate phi[] and theta[] arrays each have unit stride, as does the stat[] vector.

If the vector length is 1 then the stride is irrelevant and so ignored. It may be set to 0.

1.10 Thread-safety 13

1.10 Thread-safety

Thanks to feedback and patches provided by Rodrigo Tobar Carrizo, as of release 5.18, WCSLIB is now completely thread-safe, with only a couple of minor provisos.

In particular, a number of new routines were introduced to preclude altering the global variables NPVMAX, NPS-MAX, and NDPMAX, which determine how much memory to allocate for storing PVi_ma, PSi_ma, DPja, and DQia keyvalues: wcsinit(), lininit(), lindist(), and disinit(). Specifically, these new routines are now used by various WC-SLIB routines, such as the header parsers, which previously temporarily altered the global variables, thus posing a thread hazard.

In addition, the Flex scanners were made reentrant and consequently should now be thread-safe. This was achieved by rewriting them as thin wrappers (with the same API) over scanners that were modified (with changed API), as required to use Flex's "reentrant" option.

For complete thread-safety, please observe the following provisos:

- The low-level routines wcsnpv(), wcsnps(), and disndp() are not thread-safe, but they are not used within WCSLIB itself other than to get (not set) the values of the global variables NPVMAX, NPSMAX, and NDPMAX. wcsinit() and disinit() only do so to get default values if the relevant parameters are not provided as function arguments. Note that wcsini() invokes wcsinit() with defaults which cause this behavior, as does disini() invoking disinit().
 - The preset values of NPVMAX(=64), NPSMAX(=8), and NDPMAX(=256) are large enough to cover most practical cases. However, it may be desirable to tailor them to avoid allocating memory that remains unused. If so, and thread-safety is an issue, then use wcsinit() and disinit() instead with the relevant values specified. This is what WCSLIB routines, such as the header parsers wcspih() and wcsbth(), do to avoid wasting memory.
- wcserr_enable() sets a static variable and so is not thread-safe. However, the error reporting facility is not
 intended to be used dynamically. If detailed error messages are required, enable wcserr when execution
 starts and don't change it.

Note that diagnostic routines that print the contents of the various structs, namely celprt(), disprt(), linprt(), prjprt(), spcprt(), tabprt(), wcsprt(), and wcsperr() use printf() which is thread-safe by the POSIX requirement on stdio. However, this is only at the function level. Where multiple threads invoke these routines simultaneously their output is likely to be interleaved.

1.11 Limits

While the FITS WCS standard imposes a limit of 99 on the number of image coordinate axes, WCSLIB has a limit of 32 on the number it can handle – enforced by wcsset(), though allowed by wcsinit(). This arises in wcsp2s() and wcss2p() from the use of the stat/] vector as a bit mask to indicate invalid pixel or world coordinate elements.

In the unlikely event that it ever becomes necessary to handle more than 32 axes, it would be a simple matter to modify the *stat[]* bit mask so that bit 32 applies to all axes beyond 31. However, it was not considered worth introducing the various tests required just for the sake of pandering to unrealistic possibilities.

In addition, wcssub() has a hard-coded limit of 32 coordinate elements (matching the *stat[]* bit mask), and likewise for tabs2p() (via a static helper function, tabvox()). While it would be a simple matter to generalise this by allocating memory from the heap, since tabvox() calls itself recursively and needs to be as fast as possible, again it was not considered worth pandering to unrealistic possibilities.

1.12 Example code, testing and verification

WCSLIB has an extensive test suite that also provides programming templates as well as demonstrations. Test programs, with names that indicate the main WCSLIB routine under test, reside in ./{C,Fortran}/test and each contains a brief description of its purpose.

The high- and middle-level test programs are more instructive for applications programming, while the low-level tests are important for verifying the integrity of the mathematical routines.

· High level:

twestab provides an example of high-level applications programming using WCSLIB and CFITSIO. It constructs an input FITS test file, specifically for testing TAB coordinates, partly using westab.keyree, and then extracts the coordinate description from it following the steps outlined in weshdr.h.

tpih1 and tpih2 verify wcspih(). The first prints the contents of the structs returned by wcspih() using wcsprt() and the second uses cpgsbox() to draw coordinate graticules. Input for these comes from a FITS WCS test header implemented as a list of keyrecords, wcs.keyrec, one keyrecord per line, together with a program, tofits, that compiles these into a valid FITS file.

tbth1 tests wcsbth() by reading a test header and printing the resulting wcsprm structs. In the process it also tests wcsfix().

tfitshdr also uses wcs.keyrec to test the generic FITS header parsing routine.

twcsfix sets up a wcsprm struct containing various non-standard constructs and then invokes wcsfix() to translate them all to standard usage.

twcslint tests the syntax checker for FITS WCS keyrecords (wcsware -l) on a specially constructed header riddled with invalid entries.

tdis3 uses wcsware to test the handling of different types of distortion functions encoded in a set of test FITS headers.

· Middle level:

twcs tests closure of wcss2p() and wcsp2s() for a number of selected projections. twcsmix verifies wcsmix() on the 1° grid of celestial longitude and latitude for a number of selected projections. It plots a test grid for each projection and indicates the location of successful and failed solutions. tdis2 and twcssub test the extraction of a coordinate description for a subimage from a wcsprm struct by wcssub().

tunits tests wcsutrne(), wcsunitse() and wcsulexe(), the units specification translator, converter and parser, either interactively or using a list of units specifications contained in units_test.

twcscompare tests particular aspects of the comparison routine, wcscompare().

· Low level:

tdis1, tlin, tlog, tprj1, tspc, tsph, tspx, and ttab1 test "closure" of the respective routines. Closure tests apply the forward and reverse transformations in sequence and compare the result with the original value. Ideally, the result should agree exactly, but because of floating point rounding errors there is usually a small discrepancy so it is only required to agree within a "closure tolerance".

tprj1 tests for closure separately for longitude and latitude except at the poles where it only tests for closure in latitude. Note that closure in longitude does not deal with angular displacements on the sky. This is appropriate for many projections such as the cylindricals where circumpolar parallels are projected at the same length as the equator. On the other hand, *tsph* does test for closure in angular displacement.

The tolerance for reporting closure discrepancies is set at 10^{-10} degree for most projections; this is slightly less than 3 microarcsec. The worst case closure figure is reported for each projection and this is usually better than the reporting tolerance by several orders of magnitude. tprj1 and tsph test closure at all

points on the 1° grid of native longitude and latitude and to within 5° of any latitude of divergence for those projections that cannot represent the full sphere. Closure is also tested at a sequence of points close to the reference point (tprj1) or pole (tsph).

Closure has been verified at all test points for SUN workstations. However, non-closure may be observed for other machines near native latitude -90° for the zenithal, cylindrical and conic equal area projections (**ZEA**, **CEA** and **COE**), and near divergent latitudes of projections such as the azimuthal perspective and stereographic projections (**AZP** and **STG**). Rounding errors may also carry points between faces of the quad-cube projections (**CSC**, **QSC**, and **TSC**). Although such excursions may produce long lists of non-closure points, this is not necessarily indicative of a fundamental problem.

Note that the inverse of the COBE quad-qube projection (CSC) is a polynomial approximation and its closure tolerance is intrinsically poor.

Although tests for closure help to verify the internal consistency of the routines they do not verify them in an absolute sense. This is partly addressed by *tcel1*, *tcel2*, *tprj2*, *ttab2* and *ttab3* which plot graticules for visual inspection of scaling, orientation, and other macroscopic characteristics of the projections.

There are also a number of other special-purpose test programs that are not automatically exercised by the test suite.

1.13 WCSLIB Fortran wrappers

The Fortran subdirectory contains wrappers, written in C, that allow Fortran programs to use WCSLIB. The wrappers have no associated C header files, nor C function prototypes, as they are only meant to be called by Fortran code. Hence the C code must be consulted directly to determine the argument lists. This resides in files with names of the form $*_f$.c. However, there are associated Fortran INCLUDE files that declare function return types and various parameter definitions. There are also BLOCK DATA modules, in files with names of the form $*_data.f$, used solely to initialise error message strings.

A prerequisite for using the wrappers is an understanding of the usage of the associated C routines, in particular the data structures they are based on. The principle difficulty in creating the wrappers was the need to manage these C structs from within Fortran, particularly as they contain pointers to allocated memory, pointers to C functions, and other structs that themselves contain similar entities.

To this end, routines have been provided to set and retrieve values of the various structs, for example WCSPUT and WCSGET for the wcsprm struct, and CELPUT and CELGET for the celprm struct. These must be used in conjunction with wrappers on the routines provided to manage the structs in C, for example WCSINIT, WCSSUB, WCSCOPY, WCSFREE, and WCSPRT which wrap wcsinit(), wcssub(), wcscopy(), wcsfree(), and wcsprt().

Compilers (e.g. gfortran) may warn of inconsistent usage of the third argument in the various *PUT and *GET routines, and as of gfortran 10, these warnings have been promoted to errors. Thus, type-specific variants are provided for each of the *PUT routines, *PTI, *PTD, and *PTC for int, double, or char[], and likewise *GTI, *GTD, and *GTC for the *GET routines. While, for brevity, we will here continue to refer to the *PUT and *GET routines, as compilers are generally becoming stricter, use of the type-specific variants is recommended.

The various *PUT and *GET routines are based on codes defined in Fortran include files (*.inc). If your Fortran compiler does not support the INCLUDE statement then you will need to include these manually in your code as necessary. Codes are defined as parameters with names like WCS_CRPIX which refers to wcsprm::crpix (if your Fortran compiler does not support long symbolic names then you will need to rename these).

The include files also contain parameters, such as WCSLEN, that define the length of an INTEGER array that must be declared to hold the struct. This length may differ for different platforms depending on how the C compiler aligns data within the structs. A test program for the C library, *twcs*, prints the size of the struct in *sizeof(int)* units and the values in the Fortran include files must equal or exceed these. On some platforms, such as Suns, it is important that the start of the INTEGER array be *aligned on a DOUBLE PRECISION boundary*, otherwise a mysterious BUS error may result. This may be achieved via an EQUIVALENCE with a DOUBLE PRECISION

variable, or by sequencing variables in a COMMON block so that the INTEGER array follows immediately after a DOUBLE PRECISION variable.

The *PUT routines set only one element of an array at a time; the final one or two integer arguments of these routines specify 1-relative array indices (N.B. not 0-relative as in C). The one exception is the prjprm::pv array.

The *PUT routines also reset the *flag* element to signal that the struct needs to be reinitialized. Therefore, if you wanted to set wcsprm::flag itself to -1 prior to the first call to WCSINIT, for example, then that WCSPUT must be the last one before the call.

The *GET routines retrieve whole arrays at a time and expect array arguments of the appropriate length where necessary. Note that they do not initialize the structs, i.e. via wcsset(), prjset(), or whatever.

A basic coding fragment is

```
INTEGER LNGIDX, STATUS
CHARACTER CTYPE1*72
INCLUDE 'wcs.inc'
WCSLEN is defined as a parameter in wcs.inc.
INTEGER WCS (WCSLEN)
DOUBLE PRECISION DUMMY
EQUIVALENCE (WCS, DUMMY)
Allocate memory and set default values for 2 axes.
STATUS = WCSPTI (WCS, WCS_FLAG, -1, 0, 0)
STATUS = WCSINI (2, WCS)
Set CRPIX1, and CRPIX2; WCS_CRPIX is defined in wcs.inc.
STATUS = WCSPTD (WCS, WCS_CRPIX, 512D0, 1, 0)
STATUS = WCSPTD (WCS, WCS_CRPIX, 512D0, 2, 0)
Set PC1_2 to 5.0 (I = 1, J = 2).
STATUS = WCSPTD (WCS, WCS_PC, 5D0, 1, 2)
Set CTYPE1 to 'RA---SIN'; N.B. must be given as CHARACTER*72.
CTYPE1 = 'RA---SIN'
STATUS = WCSPTC (WCS, WCS_CTYPE, CTYPE1, 1, 0)
Use an alternate method to set CTYPE2.
STATUS = WCSPTC (WCS, WCS_CTYPE, 'DEC--SIN'//CHAR(0), 2, 0)
Set PV1_3 to -1.0 (I = 1, M = 3).
STATUS = WCSPTD (WCS, WCS_PV, -1D0, 1, 3)
etc.
Initialize.
STATUS = WCSSET (WCS)
IF (STATUS.NE.O) THEN
  CALL FLUSH (6)
  STATUS = WCSPERR (WCS, 'EXAMPLE: '//CHAR(0))
ENDIF
Find the "longitude" axis.
STATUS = WCSGTI (WCS, WCS_LNG, LNGIDX)
Free memory.
STATUS = WCSFREE (WCS)
```

Refer to the various Fortran test programs for further programming examples. In particular, *twcs* and *twcsmix* show how to retrieve elements of the celprm and priprm structs contained within the wcsprm struct.

Treatment of CHARACTER arguments in wrappers such as SPCTYPE, SPECX, and WCSSPTR, depends on whether they are given or returned. Where a CHARACTER variable is returned, its length must match the declared length in the definition of the C wrapper. The terminating null character in the C string, and all following it up

1.14 PGSBOX 17

to the declared length, are replaced with blanks. If the Fortran CHARACTER variable were shorter than the declared length, an out-of-bounds memory access error would result. If longer, the excess, uninitialized, characters could contain garbage.

If the CHARACTER argument is given, a null-terminated CHARACTER variable may be provided as input, e.g. constructed using the Fortran CHAR (0) intrinsic as in the example code above. The wrapper makes a character-by-character copy, searching for a NULL character in the process. If it finds one, the copy terminates early, resulting in a valid C string. In this case any trailing blanks before the NULL character are preserved if it makes sense to do so, such as in setting a prefix for use by the *PERR wrappers, such as WCSPERR in the example above. If a NULL is not found, then the CHARACTER argument must be at least as long as the declared length, and any trailing blanks are stripped off. Should a CHARACTER argument exceed the declared length, the excess characters are ignored.

There is one exception to the above caution regarding CHARACTER arguments. The WCSLIB_VERSION wrapper is unusual in that it provides for the length of its CHARACTER argument to be specified, and only so many characters as fit within that length are returned.

Note that the data type of the third argument to the *PUT (or *PTI, *PTD, or *PTC) and *GET (or *GTI, *GTD, or *GTC) routines differs depending on the data type of the corresponding C struct member, be it *int*, *double*, or *char*[]. It is essential that the Fortran data type match that of the C struct for *int* and *double* types, and be a CHARACTER variable of the correct length for *char*[] types, or else be null-terminated, as in the coding example above. As a further example, in the two equivalent calls

```
STATUS = PRJGET (PRJ, PRJ_NAME, NAME)
STATUS = PRJGTC (PRJ, PRJ_NAME, NAME)
```

which return a character string, NAME must be a CHARACTER variable of length 40, as declared in the priprm struct, no less and no more, the comments above pertaining to wrappers that contain CHARACTER arguments also applying here. However, a few exceptions have been made to simplify coding. The relevant *PUT (or *PTC) wrappers allow unterminated CHARACTER variables of less than the declared length for the following: prjprm::code (3 characters), spcprm::type (4 characters), spcprm::code (3 characters), and fitskeyid::name (8 characters). It doesn't hurt to specify longer CHARACTER variables, but the trailing characters will be ignored. Notwithstanding this simplification, the length of the corresponding variables in the *GET (or *GTC) wrappers must match the length declared in the struct.

When calling wrappers for C functions that print to stdout, such as WCSPET, and WCSPERR, or that may print to stderr, such as WCSPIH, WCSBTH, WCSULEXE, or WCSUTRNE, it may be necessary to flush the Fortran I/O buffers beforehand so that the output appears in the correct order. The wrappers for these functions do call fflush (\leftarrow NULL), but depending on the particular system, this may not succeed in flushing the Fortran I/O buffers. Most Fortran compilers provide the non-standard intrinsic FLUSH(), which is called with unit number 6 to flush stdout (as in the example above), and unit 0 for stderr.

A basic assumption made by the wrappers is that an INTEGER variable is no less than half the size of a DOUBLE PRECISION.

1.14 PGSBOX

PGSBOX, which is provided as a separate part of WCSLIB, is a PGPLOT routine (PGPLOT being a Fortran graphics library) that draws and labels curvilinear coordinate grids. Example PGSBOX grids can be seen at httpc//www.atnf.csiro.au/people/Mark.Calabretta/WCS/PGSBOX/index.html.

The prologue to pgsbox.f contains usage instructions. pgtest.f and cpgtest.c serve as test and demonstration programs in Fortran and C and also as well-documented examples of usage.

PGSBOX requires a separate routine, EXTERNAL NLFUNC, to define the coordinate transformation. Fortran subroutine PGCRFN (pgcrfn.f) is provided to define separable pairs of non-linear coordinate systems. Linear, logarithmic

and power-law axis types are currently defined; further types may be added as required. A C function, $pgwcsl \leftarrow _()$, with Fortran-like interface defines an NLFUNC that interfaces to WCSLIB 4.x for PGSBOX to draw celestial coordinate grids.

PGPLOT is implemented as a Fortran library with a set of C wrapper routines that are generated by a software tool. However, PGSBOX has a more complicated interface than any of the standard PGPLOT routines, especially in having an EXTERNAL function in its argument list. Consequently, PGSBOX is implemented in Fortran but with a hand-coded C wrapper, *cpgsbox()*.

As an example, in this suite the C test/demo program, *cpgtest*, calls the C wrapper, *cpgsbox()*, passing it a pointer to *pgwcsl_()*. In turn, *cpgsbox()* calls PGSBOX, which invokes *pgwcsl_()* as an EXTERNAL subroutine. In this sequence, a complicated C struct defined by *cpgtest* is passed through PGSBOX to *pgwcsl_()* as an INTEGER array.

While there are no formal standards for calling Fortran from C, there are some fairly well established conventions. Nevertheless, it's possible that you may need to modify the code if you use a combination of Fortran and C compilers with linkage conventions that differ from that of the GNU compilers, gcc and g77.

1.15 WCSLIB version numbers

The full WCSLIB/PGSBOX version number is composed of three integers in fields separated by periods:

• **Major**: the first number changes only when the ABI changes, a rare occurrence (and the API never changes). Typically, the ABI changes when the contents of a struct change. For example, the contents of the *linprm* struct changed between 4.25.1 and 5.0.

In practical terms, this number becomes the major version number of the WCSLIB sharable library, **libwcs.** \leftarrow **so.** < **major**>. To avoid possible segmentation faults or bus errors that may arise from the altered ABI, the dynamic (runtime) linker will not allow an application linked to a sharable library with a particular major version number to run with that of a different major version number.

Application code must be recompiled and relinked to use a newer version of the WCSLIB sharable library with a new major version number.

Minor: the second number changes when existing code is changed, whether due to added functionality or bug fixes. This becomes the minor version number of the WCSLIB sharable library, libwcs.
 — so.
 major>.<minor>.

Because the ABI remains unchanged, older applications can use the new sharable library without needing to be recompiled, thus obtaining the benefit of bug fixes, speed enhancements, etc.

Application code written subsequently to use the added functionality would, of course, need to be recompiled.

• Patch: the third number, which is often omitted, indicates a change to the build procedures, documentation, or test suite. It may also indicate changes to the utility applications (*wcsware*, *HPXcvt*, etc.), including the addition of new ones.

However, the library itself, including the definitions in the header files, remains unaltered, so there is no point in recompiling applications.

The following describes what happens (or should happen) when WCSLIB's installation procedures are used on a typical Linux system using the GNU gcc compiler and GNU linker.

The sharable library should be installed as libwcs.so.<*major*>.<*minor*>, say libwcs.so.5.4 for concreteness, and a number of symbolic links created as follows:

```
libwcs.so.5 -> libwcs.so.5.4 libwcs.so.5.4
```

2 Deprecated List

When an application is linked using '-lwcs', the linker finds libwcs.so and the symlinks lead it to libwcs.so.5.4. However, that library's SONAME is actually 'libwcs.so.5', by virtue of linker options used when the sharable library was created, as can be seen by running

```
readelf -d libwcs.so.5.4
```

Thus, when an application that was compiled and linked to libwcs.so.5.4 begins execution, the dynamic linker, ld.so, will attempt to bind it to libwcs.so.5, as can be seen by running

```
ldd <application>
```

Later, when WCSLIB 5.5 is installed, the library symbolic links will become

```
libwcs.so -> libwcs.so.5
libwcs.so.5 -> libwcs.so.5.5
libwcs.so.5.4
libwcs.so.5.5
```

Thus, even without being recompiled, existing applications will link automatically to libwcs.so.5.5 at runtime. In fact, libwcs.so.5.4 would no longer be used and could be deleted.

If WCSLIB 6.0 were to be installed at some later time, then the libwcs.so.6 libraries would be used for new compilations. However, the libwcs.so.5 libraries must be left in place for existing executables that still require them:

```
libwcs.so -> libwcs.so.6
libwcs.so.6 -> libwcs.so.6.0
libwcs.so.5 -> libwcs.so.5.5
libwcs.so.5.5
```

- double dummy [2]

5.1.1 Detailed Description

Additional auxiliary parameters.

The **auxprm** struct holds auxiliary coordinate system information of a specialist nature. It is anticipated that this struct will expand in future to accommodate additional parameters.

All members of this struct are to be set by the user.

5.1.2 Field Documentation

rsun ref

double auxprm::rsun_ref

(Given, auxiliary) Reference radius of the Sun used in coordinate calculations (m).

dsun_obs

```
double auxprm::dsun_obs
```

(Given, auxiliary) Distance between the centre of the Sun and the observer (m).

crln_obs

```
double auxprm::crln_obs
```

(Given, auxiliary) Carrington heliographic longitude of the observer (deg).

hgln_obs

```
double auxprm::hgln_obs
```

(Given, auxiliary) Stonyhurst heliographic longitude of the observer (deg).

hglt_obs

```
double auxprm::hglt_obs
```

(Given, auxiliary) Heliographic latitude (Carrington or Stonyhurst) of the observer (deg).

a_radius

```
double auxprm::a_radius
```

Length of the semi-major axis of a triaxial ellipsoid approximating the shape of a body (e.g. planet) in the solar system (m).

b_radius

```
double auxprm::b_radius
```

Length of the intermediate axis, normal to the semi-major and semi-minor axes, of a triaxial ellipsoid approximating the shape of a body (m).

c_radius

```
double auxprm::c_radius
```

Length of the semi-minor axis, normal to the semi-major axis, of a triaxial ellipsoid approximating the shape of a body (m).

blon_obs

```
double auxprm::blon_obs
```

Bodycentric longitude of the observer in the coordinate system fixed to the planet or other solar system body (deg, in range 0 to 360).

blat_obs

```
double auxprm::blat_obs
```

Bodycentric latitude of the observer in the coordinate system fixed to the planet or other solar system body (deg).

bdis_obs

```
double auxprm::bdis_obs
```

Bodycentric distance of the observer (m).

dummy

```
double auxprm::dummy[2]
```

5.2 celprm Struct Reference

Celestial transformation parameters.

```
#include <cel.h>
```

Data Fields

- int offset
- double phi0
- double theta0
- double ref [4]
- struct prjprm prj
- double euler [5]
- int latpreq
- int isolat
- struct wcserr * err
- void * padding

5.2.1 Detailed Description

Celestial transformation parameters.

The **celprm** struct contains information required to transform celestial coordinates. It consists of certain members that must be set by the user (*given*) and others that are set by the WCSLIB routines (*returned*). Some of the latter are supplied for informational purposes and others are for internal use only.

Returned **celprm** struct members must not be modified by the user.

5.2.2 Field Documentation

flag

```
int celprm::flag
```

(Given and returned) This flag must be set to zero (or 1, see celset()) whenever any of the following **celprm** struct members are set or changed:

- · celprm::offset,
- · celprm::phi0,
- · celprm::theta0,
- · celprm::ref[4],
- · celprm::prj:
 - prjprm::code,
 - prjprm::r0,
 - prjprm::pv[],
 - prjprm::phi0,
 - prjprm::theta0.

This signals the initialization routine, celset(), to recompute the returned members of the **celprm** struct. celset() will reset flag to indicate that this has been done.

offset

```
int celprm::offset
```

(*Given*) If true (non-zero), an offset will be applied to (x,y) to force (x,y) = (0,0) at the fiducial point, (ϕ_0 , θ_0). Default is 0 (false).

phi0

```
double celprm::phi0
```

(*Given*) The native longitude, ϕ_0 [deg], and ...

theta0

```
double celprm::theta0
```

(*Given*) ... the native latitude, θ_0 [deg], of the fiducial point, i.e. the point whose celestial coordinates are given in celprm::ref[1:2]. If undefined (set to a magic value by prjini()) the initialization routine, celset(), will set this to a projection-specific default.

ref

```
double celprm::ref
```

(*Given*) The first pair of values should be set to the celestial longitude and latitude of the fiducial point [deg] - typically right ascension and declination. These are given by the **CRVAL**ia keywords in FITS.

(Given and returned) The second pair of values are the native longitude, ϕ_p [deg], and latitude, θ_p [deg], of the celestial pole (the latter is the same as the celestial latitude of the native pole, δ_p) and these are given by the FITS keywords **LONPOLE**a and **LATPOLE**a (or by **PV**i_2a and **PV**i_3a attached to the longitude axis which take precedence if defined).

LONPOLE a defaults to ϕ_0 (see above) if the celestial latitude of the fiducial point of the projection is greater than or equal to the native latitude, otherwise ϕ_0 + 180 [deg]. (This is the condition for the celestial latitude to increase in the same direction as the native latitude at the fiducial point.) ref[2] may be set to **UNDEFINED** (from wcsmath.h) or 999.0 to indicate that the correct default should be substituted.

 $\theta_{\rm p}$, the native latitude of the celestial pole (or equally the celestial latitude of the native pole, $\delta_{\rm p}$) is often determined uniquely by CRVALia and LONPOLEa in which case LATPOLEa is ignored. However, in some circumstances there are two valid solutions for $\theta_{\rm p}$ and LATPOLEa is used to choose between them. LATPOLEa is set in ref[3] and the solution closest to this value is used to reset ref[3]. It is therefore legitimate, for example, to set ref[3] to +90.0 to choose the more northerly solution - the default if the LATPOLEa keyword is omitted from the FITS header. For the special case where the fiducial point of the projection is at native latitude zero, its celestial latitude is zero, and LONPOLEa = \pm 90.0 then the celestial latitude of the native pole is not determined by the first three reference values and LATPOLEa specifies it completely.

The returned value, celprm::latpreq, specifies how LATPOLEa was actually used.

prj

```
struct prjprm celprm::prj
```

(Given and returned) Projection parameters described in the prologue to prj.h.

euler

```
double celprm::euler
```

(*Returned*) Euler angles and associated intermediaries derived from the coordinate reference values. The first three values are the Z-, X-, and Z'-Euler angles [deg], and the remaining two are the cosine and sine of the X-Euler angle.

latpreq

```
int celprm::latpreq
```

(Returned) For informational purposes, this indicates how the LATPOLE a keyword was used

- 0: Not required, θ_p (== δ_p) was determined uniquely by the CRVALia and LONPOLEa keywords.
- 1: Required to select between two valid solutions of $\theta_{\rm p}.$
- 2: $\theta_{\rm p}$ was specified solely by ${\tt LATPOLE}_{\tt a}.$

isolat

```
int celprm::isolat
```

(*Returned*) True if the spherical rotation preserves the magnitude of the latitude, which occurs iff the axes of the native and celestial coordinates are coincident. It signals an opportunity to cache intermediate calculations common to all elements in a vector computation.

err

```
struct wcserr * celprm::err
```

(*Returned*) If enabled, when an error status is returned, this struct contains detailed information about the error, see wcserr_enable().

padding

```
void * celprm::padding
```

(An unused variable inserted for alignment purposes only.)

5.3.1 Detailed Description

Distortion parameters.

The **disprm** struct contains all of the information required to apply a set of distortion functions. It consists of certain members that must be set by the user (*given*) and others that are set by the WCSLIB routines (*returned*). While the addresses of the arrays themselves may be set by disinit() if it (optionally) allocates memory, their contents must be set by the user.

5.3.2 Field Documentation

flag

```
int disprm::flag
```

(Given and returned) This flag must be set to zero (or 1, see disset()) whenever any of the following **disprm** members are set or changed:

- · disprm::naxis,
- · disprm::dtype,
- · disprm::ndp,
- · disprm::dp.

This signals the initialization routine, disset(), to recompute the returned members of the **disprm** struct. disset() will reset flag to indicate that this has been done.

PLEASE NOTE: flag must be set to -1 when disinit() is called for the first time for a particular disprm struct in order to initialize memory management. It must ONLY be used on the first initialization otherwise memory leaks may result.

naxis

```
int disprm::naxis
```

(Given or returned) Number of pixel and world coordinate elements.

If disinit() is used to initialize the **disprm** struct (as would normally be the case) then it will set naxis from the value passed to it as a function argument. The user should not subsequently modify it.

dtype

```
disprm::dtype
```

(Given) Pointer to the first element of an array of char[72] containing the name of the distortion function for each axis.

ndp

```
int disprm::ndp
```

(Given) The number of entries in the disprm::dp[] array.

ndpmax

```
int disprm::ndpmax
```

(Given) The length of the disprm::dp[] array.

ndpmax will be set by disinit() if it allocates memory for disprm::dp[], otherwise it must be set by the user. See also disndp().

dp

```
struct dpkey disprm::dp
```

(Given) Address of the first element of an array of length ndpmax of dpkey structs.

As a FITS header parser encounters each <code>DPja</code> or <code>DQia</code> keyword it should load it into a dpkey struct in the array and increment ndp. However, note that a single <code>disprm</code> struct must hold only <code>DPja</code> or <code>DQia</code> keyvalues, not both. <code>disset()</code> interprets them as required by the particular distortion function.

totdis

```
double disprm::totdis
```

(*Given*) The maximum absolute value of the combination of all distortion functions specified as an offset in pixel coordinates computed over the whole image.

It is not necessary to reset the disprm struct (via disset()) when disprm::totdis is changed.

maxdis

```
double * disprm::maxdis
```

(*Given*) Pointer to the first element of an array of double specifying the maximum absolute value of the distortion for each axis computed over the whole image.

It is not necessary to reset the disprm struct (via disset()) when disprm::maxdis is changed.

docorr

```
int * disprm::docorr
```

(Returned) Pointer to the first element of an array of int containing flags that indicate the mode of correction for each axis.

If docorr is zero, the distortion function returns the corrected coordinates directly. Any other value indicates that the distortion function computes a correction to be added to pixel coordinates (prior distortion) or intermediate pixel coordinates (sequent distortion).

Nhat

```
int * disprm::Nhat
```

(*Returned*) Pointer to the first element of an array of int containing the number of coordinate axes that form the independent variables of the distortion function for each axis.

axmap

```
int ** disprm::axmap
```

(*Returned*) Pointer to the first element of an array of int* containing pointers to the first elements of the axis mapping arrays for each axis.

An axis mapping associates the independent variables of a distortion function with the 0-relative image axis number. For example, consider an image with a spectrum on the first axis (axis 0), followed by RA (axis 1), Dec (axis2), and time (axis 3) axes. For a distortion in (RA,Dec) and no distortion on the spectral or time axes, the axis mapping arrays, axmap[j][], would be

```
j=0: [-1, -1, -1, -1] ...no distortion on spectral axis,
1: [1, 2, -1, -1] ...RA distortion depends on RA and Dec,
2: [2, 1, -1, -1] ...Dec distortion depends on Dec and RA,
3: [-1, -1, -1, -1] ...no distortion on time axis,
```

where -1 indicates that there is no corresponding independent variable.

offset

```
double ** disprm::offset
```

(*Returned*) Pointer to the first element of an array of double* containing pointers to the first elements of arrays of offsets used to renormalize the independent variables of the distortion function for each axis.

The offsets are subtracted from the independent variables before scaling.

scale

```
double ** disprm::scale
```

(*Returned*) Pointer to the first element of an array of double* containing pointers to the first elements of arrays of scales used to renormalize the independent variables of the distortion function for each axis.

The scale is applied to the independent variables after the offsets are subtracted.

iparm

```
int ** disprm::iparm
```

(*Returned*) Pointer to the first element of an array of int* containing pointers to the first elements of the arrays of integer distortion parameters for each axis.

dparm

```
double ** disprm::dparm
```

(*Returned*) Pointer to the first element of an array of double* containing pointers to the first elements of the arrays of floating point distortion parameters for each axis.

i_naxis

```
int disprm::i_naxis
```

(Returned) Dimension of the internal arrays (normally equal to naxis).

ndis

```
int disprm::ndis
```

(Returned) The number of distortion functions.

err

```
struct wcserr * disprm::err
```

(*Returned*) If enabled, when an error status is returned, this struct contains detailed information about the error, see wcserr_enable().

disp2x

```
int(** disprm::disp2x) (DISP2X_ARGS)
```

(For internal use only.)

disx2p

```
int(** disprm::disx2p) (DISX2P_ARGS)
(For internal use only.)
m_flag
int disprm::m_flag
(For internal use only.)
m_naxis
int disprm::m_naxis
(For internal use only.)
m_dtype
disprm::m_dtype
(For internal use only.)
m_dp
double ** disprm::m_dp
(For internal use only.)
m_maxdis
double * disprm::m_maxdis
(For internal use only.)
```

5.4 dpkey Struct Reference

Store for \mathtt{DP} ja and \mathtt{DQ} ia keyvalues.

#include <dis.h>

Data Fields

```
char field [72]
int j
int type
union {
    int i
    double f
    } value
```

5.4.1 Detailed Description

Store for DP ja and DQia keyvalues.

The **dpkey** struct is used to pass the parsed contents of **DP** ja or **DQ**ia keyrecords to disset() via the disprm struct. A disprm struct must hold only **DP** ja or **DQ**ia keyvalues, not both.

All members of this struct are to be set by the user.

5.4.2 Field Documentation

field

```
char dpkey::field
```

(*Given*) The full field name of the record, including the keyword name. Note that the colon delimiter separating the field name and the value in record-valued keyvalues is not part of the field name. For example, in the following:

DP3A = 'AXIS.1: 2'

the full record field name is "DP3A.AXIS.1", and the record's value is 2.

```
j
```

```
int dpkey::j
```

(Given) Axis number (1-relative), i.e. the j in DP ja or i in DQia.

type

```
int dpkey::type
```

(Given) The data type of the record's value

- 0: Integer (stored as an int),
- 1: Floating point (stored as a double).

the record's value.

5.5 fitskey Struct Reference

Keyword/value information.

```
#include <fitshdr.h>
```

Data Fields

```
int keyno
int keyid
int status
char keyword [12]
int type
int padding
union {
    int i
    int64 k
    int I [8]
    double f
    double c [2]
    char s [72]
} keyvalue
```

- int ulen
- char comment [84]

5.5.1 Detailed Description

Keyword/value information.

fitshdr() returns an array of **fitskey** structs, each of which contains the result of parsing one FITS header keyrecord. All members of the **fitskey** struct are returned by **fitshdr()**, none are given by the user.

5.5.2 Field Documentation

keyno

```
int fitskey::keyno
```

(*Returned*) Keyrecord number (1-relative) in the array passed as input to fitshdr(). This will be negated if the keyword matched any specified in the keyids[] index.

keyid

```
int fitskey::keyid
```

(Returned) Index into the first entry in keyids[] with which the keyrecord matches, else -1.

status

```
int fitskey::status
```

(*Returned*) Status flag bit-vector for the header keyrecord employing the following bit masks defined as preprocessor macros:

- FITSHDR_KEYWORD: Illegal keyword syntax.
- FITSHDR_KEYVALUE: Illegal keyvalue syntax.
- FITSHDR_COMMENT: Illegal keycomment syntax.
- FITSHDR_KEYREC: Illegal keyrecord, e.g. an **END** keyrecord with trailing text.
- FITSHDR_TRAILER: Keyrecord following a valid **END** keyrecord.

The header keyrecord is syntactically correct if no bits are set.

keyword

```
char fitskey::keyword
```

(Returned) Keyword name, null-filled for keywords of less than eight characters (trailing blanks replaced by nulls).

Use

```
sprintf(dst, "%.8s", keyword)
```

```
to copy it to a character array with null-termination, or sprintf(dst, "%8.8s", keyword)
```

to blank-fill to eight characters followed by null-termination.

type

```
int fitskey::type
```

(Returned) Keyvalue data type:

- 0: No keyvalue (both the value and type are undefined).
- · 1: Logical, represented as int.
- 2: 32-bit signed integer.
- 3: 64-bit signed integer (see below).
- · 4: Very long integer (see below).
- 5: Floating point (stored as double).
- 6: Integer complex (stored as double[2]).
- 7: Floating point complex (stored as double[2]).
- · 8: String.
- 8+10*n: Continued string (described below and in fitshdr() note 2).

A negative type indicates that a syntax error was encountered when attempting to parse a keyvalue of the particular type.

Comments on particular data types:

• 64-bit signed integers lie in the range (-9223372036854775808 <= int64 < -2147483648) || (+2147483647 < int64 <= +9223372036854775807)

A native 64-bit data type may be defined via preprocessor macro WCSLIB_INT64 defined in wcsconfig.h, e.g. as 'long long int'; this will be typedef'd to 'int64' here. If WCSLIB_INT64 is not set, then int64 is typedef'd to int[3] instead and fitskey::keyvalue is to be computed as

where keyvalue.k[0] and keyvalue.k[1] range from -999999999 to +999999999.

Very long integers, up to 70 decimal digits in length, are encoded in keyvalue. I as an array of int[8], each of which stores 9 decimal digits. fitskey::keyvalue is to be computed as

Continued strings are not reconstructed, they remain split over successive fitskey structs in the keys[] array returned by fitshdr(). fitskey::keyvalue data type, 8 + 10n, indicates the segment number, n, in the continuation.

padding

```
int fitskey::padding
(An unused variable inserted for alignment purposes only.)
i
int fitskey::i
(Returned) Logical (fitskey::type == 1) and 32-bit signed integer (fitskey::type == 2) data types in the fitskey::keyvalue
union.
k
int64 fitskey::k
(Returned) 64-bit signed integer (fitskey::type == 3) data type in the fitskey::keyvalue union.
ī
int fitskey::1
(Returned) Very long integer (fitskey::type == 4) data type in the fitskey::keyvalue union.
f
double fitskey::f
(Returned) Floating point (fitskey::type == 5) data type in the fitskey::keyvalue union.
С
double fitskey::c
(Returned) Integer and floating point complex (fitskey::type == 6 | 7) data types in the fitskey::keyvalue union.
s
char fitskey::s
(Returned) Null-terminated string (fitskey::type == 8) data type in the fitskey::keyvalue union.
```

keyvalue

```
union fitskey::keyvalue
```

(Returned) A union comprised of

- fitskey::i,
- · fitskey::k,
- · fitskey::l,
- · fitskey::f,
- · fitskey::c,
- · fitskey::s,

used by the fitskey struct to contain the value associated with a keyword.

ulen

```
int fitskey::ulen
```

(*Returned*) Where a keycomment contains a units string in the standard form, e.g. [m/s], the ulen member indicates its length, inclusive of square brackets. Otherwise ulen is zero.

comment

```
char fitskey::comment
```

(*Returned*) Keycomment, i.e. comment associated with the keyword or, for keyrecords rejected because of syntax errors, the compete keyrecord itself with null-termination.

Comments are null-terminated with trailing spaces removed. Leading spaces are also removed from keycomments (i.e. those immediately following the '/' character), but not from **COMMENT** or **HISTORY** keyrecords or keyrecords without a value indicator ("= " in columns 9-80).

5.6 fitskeyid Struct Reference

Keyword indexing.

```
#include <fitshdr.h>
```

Data Fields

- char name [12]
- int count
- int idx [2]

5.6.1 Detailed Description

Keyword indexing.

fitshdr() uses the **fitskeyid** struct to return indexing information for specified keywords. The struct contains three members, the first of which, fitskeyid::name, must be set by the user with the remainder returned by fitshdr().

5.6.2 Field Documentation

name

```
char fitskeyid::name
```

(*Given*) Name of the required keyword. This is to be set by the user; the '.' character may be used for wildcarding. Trailing blanks will be replaced with nulls.

count

```
int fitskeyid::count
```

(Returned) The number of matches found for the keyword.

idx

```
int fitskeyid::idx
```

(*Returned*) Indices into keys[], the array of fitskey structs returned by fitshdr(). Note that these are 0-relative array indices, not keyrecord numbers.

If the keyword is found in the header the first index will be set to the array index of its first occurrence, otherwise it will be set to -1.

If multiples of the keyword are found, the second index will be set to the array index of its last occurrence, otherwise it will be set to -1.

5.7 linprm Struct Reference

Linear transformation parameters.

```
#include <lin.h>
```

Data Fields

- int flag
- · int naxis
- double * crpix
- double * pc
- double * cdelt
- struct disprm * dispre
- struct disprm * disseq
- double * piximg
- double * imgpix
- int i naxis
- int unity
- · int affine
- int simple
- struct wcserr * err
- double * tmpcrd
- int m_flag
- int m_naxis
- double * m_crpix
- double * m_pc
- double * m cdelt
- struct disprm * m_dispre
- struct disprm * m_disseq

5.7.1 Detailed Description

Linear transformation parameters.

The **linprm** struct contains all of the information required to perform a linear transformation. It consists of certain members that must be set by the user (*given*) and others that are set by the WCSLIB routines (*returned*).

5.7.2 Field Documentation

flag

```
int linprm::flag
```

(Given and returned) This flag must be set to zero (or 1, see linset()) whenever any of the following **linprm** members are set or changed:

- linprm::naxis (q.v., not normally set by the user),
- · linprm::pc,
- · linprm::cdelt,
- · linprm::dispre.
- · linprm::disseq.

This signals the initialization routine, linset(), to recompute the returned members of the **linprm** struct. linset() will reset flag to indicate that this has been done.

PLEASE NOTE: flag should be set to -1 when lininit() is called for the first time for a particular **linprm** struct in order to initialize memory management. It must ONLY be used on the first initialization otherwise memory leaks may result.

naxis

```
int linprm::naxis
```

(Given or returned) Number of pixel and world coordinate elements.

If lininit() is used to initialize the **linprm** struct (as would normally be the case) then it will set naxis from the value passed to it as a function argument. The user should not subsequently modify it.

crpix

```
double * linprm::crpix
```

(Given) Pointer to the first element of an array of double containing the coordinate reference pixel, CRPIX ja.

It is not necessary to reset the **linprm** struct (via linset()) when linprm::crpix is changed.

рс

```
double * linprm::pc
```

(*Given*) Pointer to the first element of the **PC**i_ja (pixel coordinate) transformation matrix. The expected order is struct linprm lin; lin.pc = {PC1_1, PC1_2, PC2_1, PC2_2};

This may be constructed conveniently from a 2-D array via

which is equivalent to

```
double m[2][2];
m[0][0] = PC1_1;
m[0][1] = PC1_2;
m[1][0] = PC2_1;
m[1][1] = PC2_2;
```

The storage order for this 2-D array is the same as for the 1-D array, whence

```
lin.pc = *m;
```

would be legitimate.

cdelt

```
double * linprm::cdelt
```

(Given) Pointer to the first element of an array of double containing the coordinate increments, CDELTia.

dispre

```
struct disprm * linprm::dispre
```

(*Given*) Pointer to a disprm struct holding parameters for prior distortion functions, or a null (0x0) pointer if there are none.

Function lindist() may be used to assign a disprm pointer to a **linprm** struct, allowing it to take control of any memory allocated for it, as in the following example:

```
void add_distortion(struct linprm *lin)
{
  struct disprm *dispre;

  dispre = malloc(sizeof(struct disprm));
  dispre->flag = -1;
  lindist(1, lin, dispre, ndpmax);
  :
   (Set up dispre.)
  :
  return;
```

Here, after the distortion function parameters etc. are copied into dispre, dispre is assigned using lindist() which takes control of the allocated memory. It will be freed later when linfree() is invoked on the linprm struct.

Consider also the following erroneous code:

```
void bad_code(struct linprm *lin)
{
  struct disprm dispre;

  dispre.flag = -1;
  lindist(1, lin, &dispre, ndpmax); // WRONG.
   :
  return;
}
```

Here, dispre is declared as a struct, rather than a pointer. When the function returns, dispre will go out of scope and its memory will most likely be reused, thereby trashing its contents. Later, a segfault will occur when linfree() tries to free dispre's stale address.

disseq

```
struct disprm * linprm::disseq
```

(*Given*) Pointer to a disprm struct holding parameters for sequent distortion functions, or a null (0x0) pointer if there are none.

Refer to the comments and examples given for disprm::dispre.

piximg

```
double * linprm::piximg
```

(*Returned*) Pointer to the first element of the matrix containing the product of the **CDELT**ia diagonal matrix and the **PC**i_ja matrix.

imgpix

```
double * linprm::imgpix
```

(Returned) Pointer to the first element of the inverse of the linprm::piximg matrix.

i_naxis

```
int linprm::i_naxis
```

(Returned) The dimension of linprm::piximg and linprm::imgpix (normally equal to naxis).

unity

```
int linprm::unity
```

(Returned) True if the linear transformation matrix is unity.

affine

```
int linprm::affine
```

(Returned) True if there are no distortions.

simple

```
int linprm::simple
```

(Returned) True if unity and no distortions.

err

```
struct wcserr * linprm::err
```

(*Returned*) If enabled, when an error status is returned, this struct contains detailed information about the error, see wcserr_enable().

tmpcrd

```
double * linprm::tmpcrd
```

(For internal use only.)

m_flag

```
int linprm::m_flag
```

(For internal use only.)

```
m_naxis
int linprm::m_naxis
(For internal use only.)
m_crpix
double * linprm::m_crpix
(For internal use only.)
m_pc
double * linprm::m_pc
(For internal use only.)
m_cdelt
double * linprm::m_cdelt
(For internal use only.)
m_dispre
struct disprm * linprm::m_dispre
(For internal use only.)
m_disseq
struct disprm * linprm::m_disseq
```

5.8 prjprm Struct Reference

Projection parameters.

(For internal use only.)

```
#include <pri.h>
```

Data Fields

- · int flag
- char code [4]
- double r0
- double pv [PVN]
- double phi0

- int simplezen
- int equiareal
- · int conformal
- int global
- · int divergent
- double x0
- double y0
- struct wcserr * err
- void * padding
- double w [10]
- int m
- int n
- int(* prjx2s)(PRJX2S_ARGS)
- int(* prjs2x)(PRJS2X_ARGS)

5.8.1 Detailed Description

Projection parameters.

The **prjprm** struct contains all information needed to project or deproject native spherical coordinates. It consists of certain members that must be set by the user (*given*) and others that are set by the WCSLIB routines (*returned*). Some of the latter are supplied for informational purposes while others are for internal use only.

5.8.2 Field Documentation

flag

```
int prjprm::flag
```

(Given and returned) This flag must be set to zero (or 1, see prjset()) whenever any of the following prjprm members are set or changed:

- · prjprm::code,
- prjprm::r0,
- prjprm::pv[],
- · prjprm::phi0,
- prjprm::theta0.

This signals the initialization routine (prjset() or ???set()) to recompute the returned members of the prjprm struct. flag will then be reset to indicate that this has been done.

Note that flag need not be reset when prjprm::bounds is changed.

code

```
char prjprm::code
```

(Given) Three-letter projection code defined by the FITS standard.

r0

```
double prjprm::r0
```

(*Given*) The radius of the generating sphere for the projection, a linear scaling parameter. If this is zero, it will be reset to its default value of $180^{\circ}/\pi$ (the value for FITS WCS).

pν

```
double prjprm::pv
```

(*Given*) Projection parameters. These correspond to the PVi_ma keywords in FITS, so pv[0] is PVi_0a , pv[1] is PVi_1a , etc., where i denotes the latitude-like axis. Many projections use pv[1] (PVi_1a), some also use pv[2] (PVi_2a) and SZP uses pv[3] (PVi_3a). ZPN is currently the only projection that uses any of the others.

Usage of the pv[] array as it applies to each projection is described in the prologue to each trio of projection routines in prj.c.

phi0

```
double prjprm::phi0
```

(*Given*) The native longitude, ϕ_0 [deg], and ...

theta0

```
double prjprm::theta0
```

(*Given*) ... the native latitude, θ_0 [deg], of the reference point, i.e. the point (x, y) = (0,0). If undefined (set to a magic value by prjini()) the initialization routine will set this to a projection-specific default.

bounds

```
int prjprm::bounds
```

(*Given*) Controls bounds checking. If bounds&1 then enable strict bounds checking for the spherical-to-Cartesian (s2x) transformation for the **AZP**, **SZP**, **TAN**, **SIN**, **ZPN**, and **COP** projections. If bounds&2 then enable strict bounds checking for the Cartesian-to-spherical transformation (x2s) for the **HPX** and XPH projections. If bounds&4 then the Cartesian- to-spherical transformations (x2s) will invoke prjbchk() to perform bounds checking on the computed native coordinates, with a tolerance set to suit each projection. bounds is set to 7 by prjini() by default which enables all checks. Zero it to disable all checking.

It is not necessary to reset the priprm struct (via priset() or ???set()) when priprm::bounds is changed.

The remaining members of the **prjprm** struct are maintained by the setup routines and must not be modified elsewhere:

name

```
char prjprm::name
```

(Returned) Long name of the projection.

Provided for information only, not used by the projection routines.

category

```
int prjprm::category
```

(Returned) Projection category matching the value of the relevant global variable:

- · ZENITHAL,
- · CYLINDRICAL,
- · PSEUDOCYLINDRICAL,
- · CONVENTIONAL,
- · CONIC,
- · POLYCONIC.
- · QUADCUBE, and
- HEALPIX.

The category name may be identified via the prj_categories character array, e.g.

```
struct prjprm prj;
...
printf("%s\n", prj_categories[prj.category]);
```

Provided for information only, not used by the projection routines.

pvrange

```
int prjprm::pvrange
```

(*Returned*) Range of projection parameter indices: 100 times the first allowed index plus the number of parameters, e.g. **TAN** is 0 (no parameters), **SZP** is 103 (1 to 3), and **ZPN** is 30 (0 to 29).

Provided for information only, not used by the projection routines.

simplezen

```
\verb"int prjprm":: \verb"simplezen"
```

(Returned) True if the projection is a radially-symmetric zenithal projection.

Provided for information only, not used by the projection routines.

equiareal

```
int prjprm::equiareal
```

(Returned) True if the projection is equal area.

Provided for information only, not used by the projection routines.

conformal

```
int prjprm::conformal
```

(Returned) True if the projection is conformal.

Provided for information only, not used by the projection routines.

global

```
int prjprm::global
```

(Returned) True if the projection can represent the whole sphere in a finite, non-overlapped mapping.

Provided for information only, not used by the projection routines.

divergent

```
int prjprm::divergent
```

(Returned) True if the projection diverges in latitude.

Provided for information only, not used by the projection routines.

х0

```
double prjprm::x0
```

(Returned) The offset in x,and ...

y0

```
double prjprm::y0
```

(*Returned*) ... the offset in y used to force (x,y) = (0,0) at (ϕ_0,θ_0).

err

```
struct wcserr * prjprm::err
```

(*Returned*) If enabled, when an error status is returned, this struct contains detailed information about the error, see wcserr_enable().

padding

```
void * prjprm::padding
```

(An unused variable inserted for alignment purposes only.)

w

```
double prjprm::w
```

(*Returned*) Intermediate floating-point values derived from the projection parameters, cached here to save recomputation.

Usage of the w[] array as it applies to each projection is described in the prologue to each trio of projection routines in prj.c.

m

int prjprm::m

n

int prjprm::n

(Returned) Intermediate integer value (used only for the ZPN and HPX projections).

prjx2s

```
prjprm::prjx2s
```

(Returned) Pointer to the spherical projection ...

prjs2x

prjprm::prjs2x

(Returned) ... and deprojection routines.

5.9 pscard Struct Reference

```
Store for {\tt PS}i\_{\tt ma} keyrecords.
```

```
#include <wcs.h>
```

Data Fields

- int i
- int m
- char value [72]

5.9.1 Detailed Description

Store for PSi_ma keyrecords.

The **pscard** struct is used to pass the parsed contents of **PS**i_ma keyrecords to wcsset() via the wcsprm struct.

All members of this struct are to be set by the user.

5.9.2 Field Documentation

```
i
```

```
int pscard::i
```

(Given) Axis number (1-relative), as in the FITS PSi_ma keyword.

m

```
int pscard::m
```

(Given) Parameter number (non-negative), as in the FITS PSi_ma keyword.

value

```
char pscard::value
```

(Given) Parameter value.

5.10 pvcard Struct Reference

Store for PVi_ma keyrecords.

```
#include <wcs.h>
```

Data Fields

- int i
- int m
- double value

5.10.1 Detailed Description

Store for PVi_ma keyrecords.

The pvcard struct is used to pass the parsed contents of PVi_ma keyrecords to wcsset() via the wcsprm struct.

All members of this struct are to be set by the user.

5.10.2 Field Documentation

i

```
int pvcard::i
```

(Given) Axis number (1-relative), as in the FITS **PV**i_ma keyword. If i == 0, wcsset() will replace it with the latitude axis number

m

```
int pvcard::m
```

(Given) Parameter number (non-negative), as in the FITS PVi_ma keyword.

value

```
double pvcard::value
```

(Given) Parameter value.

5.11 spcprm Struct Reference

Spectral transformation parameters.

```
#include <spc.h>
```

Data Fields

- · int flag
- char type [8]
- char code [4]
- double crval
- · double restfrq
- · double restway
- double pv [7]
- double w [6]
- int isGrism
- int padding1
- struct wcserr * err
- void * padding2
- int(* spxX2P)(SPX_ARGS)
- int(* spxP2S)(SPX_ARGS)
- int(* spxS2P)(SPX_ARGS)
- int(* spxP2X)(SPX_ARGS)

5.11.1 Detailed Description

Spectral transformation parameters.

The **spcprm** struct contains information required to transform spectral coordinates. It consists of certain members that must be set by the user (*given*) and others that are set by the WCSLIB routines (*returned*). Some of the latter are supplied for informational purposes while others are for internal use only.

5.11.2 Field Documentation

flag

```
int spcprm::flag
```

(Given and returned) This flag must be set to zero (or 1, see spcset()) whenever any of the following **spcprm** members are set or changed:

- spcprm::type,
- · spcprm::code,
- · spcprm::crval,
- · spcprm::restfrq,
- spcprm::restwav,
- spcprm::pv[].

This signals the initialization routine, spcset(), to recompute the returned members of the **spcprm** struct. spcset() will reset flag to indicate that this has been done.

type

```
char spcprm::type
```

(Given) Four-letter spectral variable type, e.g "ZOPT" for CTYPEia = 'ZOPT-F2W'. (Declared as char[8] for alignment reasons.)

code

```
char spcprm::code
```

(Given) Three-letter spectral algorithm code, e.g "F2W" for CTYPEia = 'ZOPT-F2W'.

crval

```
double spcprm::crval
```

(Given) Reference value (CRVALia), SI units.

restfrq

```
double spcprm::restfrq
```

(Given) The rest frequency [Hz], and ...

restwav

```
double spcprm::restwav
```

(Given) ... the rest wavelength in vacuo [m], only one of which need be given, the other should be set to zero. Neither are required if the X and S spectral variables are both wave-characteristic, or both velocity-characteristic, types.

pν

```
double spcprm::pv
```

(Given) Grism parameters for 'GRI' and 'GRA' algorithm codes:

- 0: G, grating ruling density.
- 1: m, interference order.
- 2: α , angle of incidence [deg].
- 3: n_r , refractive index at the reference wavelength, λ_r .
- 4: n'_r , $dn/d\lambda$ at the reference wavelength, λ_r (/m).
- 5: ϵ , grating tilt angle [deg].
- 6: θ , detector tilt angle [deg].

The remaining members of the **spcprm** struct are maintained by **spcset()** and must not be modified elsewhere:

W

```
double spcprm::w
```

(Returned) Intermediate values:

- 0: Rest frequency or wavelength (SI).
- 1: The value of the *X*-type spectral variable at the reference point (SI units).
- 2: dX/dS at the reference point (SI units).

The remainder are grism intermediates.

isGrism

```
int spcprm::isGrism
```

(Returned) Grism coordinates?

- 0: no,
- · 1: in vacuum,
- 2: in air.

padding1

```
int spcprm::padding1
```

(An unused variable inserted for alignment purposes only.)

err

```
struct wcserr * spcprm::err
```

(*Returned*) If enabled, when an error status is returned, this struct contains detailed information about the error, see wcserr_enable().

padding2

```
void * spcprm::padding2
```

(An unused variable inserted for alignment purposes only.)

spxX2P

```
spcprm::spxX2P
```

(Returned) The first and ...

spxP2S

```
spcprm::spxP2S
```

(Returned) ... the second of the pointers to the transformation functions in the two-step algorithm chain $X \leadsto P \to S$ in the pixel-to-spectral direction where the non-linear transformation is from X to P. The argument list, SPX_ARGS, is defined in spx.h.

spxS2P

```
spcprm::spxS2P
```

(Returned) The first and ...

spxP2X

```
spcprm::spxP2X
```

(Returned) ... the second of the pointers to the transformation functions in the two-step algorithm chain $S \to P \leadsto X$ in the spectral-to-pixel direction where the non-linear transformation is from P to X. The argument list, SPX_ARGS, is defined in spx.h.

5.12.1 Detailed Description

Spectral variables and their derivatives.

The **spxprm** struct contains the value of all spectral variables and their derivatives. It is used solely by **specx()** which constructs it from information provided via its function arguments.

This struct should be considered read-only, no members need ever be set nor should ever be modified by the user.

5.12.2 Field Documentation

restfrq

double spxprm::restfrq

(Returned) Rest frequency [Hz].

restwav

double spxprm::restwav

(Returned) Rest wavelength [m].

wavetype

```
int spxprm::wavetype
```

(Returned) True if wave types have been computed, and ...

velotype

```
int spxprm::velotype
```

(Returned) ... true if velocity types have been computed; types are defined below.

If one or other of spxprm::restfrq and spxprm::restwav is given (non-zero) then all spectral variables may be computed. If both are given, restfrq is used. If restfrq and restwav are both zero, only wave characteristic xor velocity type spectral variables may be computed depending on the variable given. These flags indicate what is available.

freq

```
double spxprm::freq
```

(Returned) Frequency [Hz] (wavetype).

afrq

double spxprm::afrq

(Returned) Angular frequency [rad/s] (wavetype).

ener

double spxprm::ener

(Returned) Photon energy [J] (wavetype).

wavn

double spxprm::wavn

(Returned) Wave number [/m] (wavetype).

vrad

double spxprm::vrad

(Returned) Radio velocity [m/s] (velotype).

wave double spxprm::wave (Returned) Vacuum wavelength [m] (wavetype). vopt double spxprm::vopt (Returned) Optical velocity [m/s] (velotype). zopt double spxprm::zopt (Returned) Redshift [dimensionless] (velotype). awav double spxprm::awav (Returned) Air wavelength [m] (wavetype). velo double spxprm::velo (Returned) Relativistic velocity [m/s] (velotype). beta double spxprm::beta (Returned) Relativistic beta [dimensionless] (velotype). dfreqafrq double spxprm::dfreqafrq (*Returned*) Derivative of frequency with respect to angular frequency [/rad] (constant, $= 1/2\pi$), and ... dafrqfreq double spxprm::dafrqfreq

(*Returned*) ... vice versa [rad] (constant, = 2π , always available).

dfreqener

```
double spxprm::dfreqener
```

(*Returned*) Derivative of frequency with respect to photon energy [/J/s] (constant, = 1/h), and ...

denerfreq

```
double spxprm::denerfreq
```

(Returned) ... vice versa [Js] (constant, = h, Planck's constant, always available).

dfreqwavn

```
double spxprm::dfreqwavn
```

(Returned) Derivative of frequency with respect to wave number [m/s] (constant, = c, the speed of light in vacuo), and ...

dwavnfreq

```
double spxprm::dwavnfreq
```

(*Returned*) ... vice versa [s/m] (constant, = 1/c, always available).

dfreqvrad

```
double spxprm::dfreqvrad
```

(Returned) Derivative of frequency with respect to radio velocity [/m], and ...

dvradfreq

```
double spxprm::dvradfreq
```

(Returned) ... vice versa [m] (wavetype && velotype).

dfreqwave

```
double spxprm::dfreqwave
```

(Returned) Derivative of frequency with respect to vacuum wavelength [/m/s], and ...

dwavefreq

```
double spxprm::dwavefreq
(Returned) ... vice versa [m s] (wavetype).
```

dfreqawav

```
double spxprm::dfreqawav
```

(Returned) Derivative of frequency with respect to air wavelength, [/m/s], and ...

dawavfreq

```
double spxprm::dawavfreq
(Returned) ... vice versa [m s] (wavetype).
```

dfreqvelo

```
double spxprm::dfreqvelo
```

(Returned) Derivative of frequency with respect to relativistic velocity [/m], and ...

dvelofreq

```
double spxprm::dvelofreq
```

(Returned) ... vice versa [m] (wavetype && velotype).

dwavevopt

```
double spxprm::dwavevopt
```

(Returned) Derivative of vacuum wavelength with respect to optical velocity [s], and ...

dvoptwave

```
double spxprm::dvoptwave
```

(Returned) ... vice versa [/s] (wavetype && velotype).

dwavezopt

```
double spxprm::dwavezopt
```

(Returned) Derivative of vacuum wavelength with respect to redshift [m], and ...

dzoptwave

```
double spxprm::dzoptwave

(Returned) ... vice versa [/m] (wavetype && velotype).
```

dwaveawav

```
double spxprm::dwaveawav
```

(Returned) Derivative of vacuum wavelength with respect to air wavelength [dimensionless], and ...

dawavwave

```
double spxprm::dawavwave
```

(Returned) ... vice versa [dimensionless] (wavetype).

dwavevelo

```
double spxprm::dwavevelo
```

(Returned) Derivative of vacuum wavelength with respect to relativistic velocity [s], and ...

dvelowave

```
double spxprm::dvelowave
```

(Returned) ... vice versa [/s] (wavetype && velotype).

dawavvelo

```
double spxprm::dawavvelo
```

(Returned) Derivative of air wavelength with respect to relativistic velocity [s], and ...

dveloawav

```
double spxprm::dveloawav
```

(Returned) ... vice versa [/s] (wavetype && velotype).

dvelobeta

```
double spxprm::dvelobeta
```

(*Returned*) Derivative of relativistic velocity with respect to relativistic beta [m/s] (constant, = c, the speed of light in vacuo), and ...

dbetavelo

```
double spxprm::dbetavelo \label{eq:constant} \textit{(Returned)} \ \dots \ \text{vice versa [s/m] (constant,} = 1/c, \ \text{always available)}.
```

err

```
struct wcserr * spxprm::err
```

(*Returned*) If enabled, when an error status is returned, this struct contains detailed information about the error, see wcserr_enable().

padding

```
void * spxprm::padding
```

(An unused variable inserted for alignment purposes only.)

5.13.1 Detailed Description

Tabular transformation parameters.

The **tabprm** struct contains information required to transform tabular coordinates. It consists of certain members that must be set by the user (*given*) and others that are set by the WCSLIB routines (*returned*). Some of the latter are supplied for informational purposes while others are for internal use only.

5.13.2 Field Documentation

flag

```
int tabprm::flag
```

(Given and returned) This flag must be set to zero (or 1, see tabset()) whenever any of the following **tabprm** members are set or changed:

- tabprm::M (q.v., not normally set by the user),
- tabprm::K (q.v., not normally set by the user),
- · tabprm::map,
- · tabprm::crval,
- · tabprm::index,
- · tabprm::coord.

This signals the initialization routine, tabset(), to recompute the returned members of the tabprm struct. tabset() will reset flag to indicate that this has been done.

PLEASE NOTE: flag should be set to -1 when tabini() is called for the first time for a particular **tabprm** struct in order to initialize memory management. It must ONLY be used on the first initialization otherwise memory leaks may result.

M

```
int tabprm::M
```

(Given or returned) Number of tabular coordinate axes.

If tabini() is used to initialize the **tabprm** struct (as would normally be the case) then it will set M from the value passed to it as a function argument. The user should not subsequently modify it.

Κ

```
int * tabprm::K
```

(Given or returned) Pointer to the first element of a vector of length tabprm::M whose elements $(K_1, K_2, ... K_M)$ record the lengths of the axes of the coordinate array and of each indexing vector.

If tabini() is used to initialize the tabprm struct (as would normally be the case) then it will set K from the array passed to it as a function argument. The user should not subsequently modify it.

map

```
int * tabprm::map
```

(*Given*) Pointer to the first element of a vector of length tabprm::M that defines the association between axis m in the M-dimensional coordinate array ($1 \le m \le M$) and the indices of the intermediate world coordinate and world coordinate arrays, x[] and world[], in the argument lists for tabx2s() and tabs2x().

When x[] and world[] contain the full complement of coordinate elements in image-order, as will usually be the case, then map[m-1] == i-1 for axis i in the N-dimensional image ($1 \le i \le N$). In terms of the FITS keywords

```
map[PVi_3a - 1] == i - 1.
```

However, a different association may result if x[], for example, only contains a (relevant) subset of intermediate world coordinate elements. For example, if M == 1 for an image with N > 1, it is possible to fill x[] with the relevant coordinate element with nelem set to 1. In this case map[0] = 0 regardless of the value of i.

crval

```
double * tabprm::crval
```

(*Given*) Pointer to the first element of a vector of length tabprm::M whose elements contain the index value for the reference pixel for each of the tabular coordinate axes.

index

```
double ** tabprm::index
```

(*Given*) Pointer to the first element of a vector of length tabprm::M of pointers to vectors of lengths $(K_1, K_2, ...K_M)$ of 0-relative indexes (see tabprm::K).

The address of any or all of these index vectors may be set to zero, i.e. index[m] = 0:

this is interpreted as default indexing, i.e.

```
index[m][k] = k;
```

coord

```
double * tabprm::coord
```

(*Given*) Pointer to the first element of the tabular coordinate array, treated as though it were defined as $double \ coord[K_M] \dots [K_2] [K_1] [M]$;

(see tabprm::K) i.e. with the M dimension varying fastest so that the M elements of a coordinate vector are stored contiguously in memory.

nc

```
int tabprm::nc
```

(*Returned*) Total number of coordinate vectors in the coordinate array being the product $K_1K_2...K_M$ (see tabprm::K).

padding

```
int tabprm::padding
```

(An unused variable inserted for alignment purposes only.)

sense

```
int * tabprm::sense
```

(*Returned*) Pointer to the first element of a vector of length tabprm::M whose elements indicate whether the corresponding indexing vector is monotonic increasing (+1), or decreasing (-1).

p0

```
int * tabprm::p0
```

(*Returned*) Pointer to the first element of a vector of length tabprm::M of interpolated indices into the coordinate array such that Υ_m , as defined in Paper III, is equal to (p0[m] + 1) + tabprm::delta[m].

delta

```
double * tabprm::delta
```

(*Returned*) Pointer to the first element of a vector of length tabprm::M of interpolated indices into the coordinate array such that Υ_m , as defined in Paper III, is equal to (tabprm::p0[m] + 1) + delta[m].

extrema

```
double * tabprm::extrema
```

(Returned) Pointer to the first element of an array that records the minimum and maximum value of each element of the coordinate vector in each row of the coordinate array, treated as though it were defined as $double extrema[K_M]...[K_2][2][M]$

(see tabprm::K). The minimum is recorded in the first element of the compressed K_1 dimension, then the maximum. This array is used by the inverse table lookup function, tabs2x(), to speed up table searches.

err

```
struct wcserr * tabprm::err
```

(*Returned*) If enabled, when an error status is returned, this struct contains detailed information about the error, see wcserr_enable().

```
m_flag
int tabprm::m_flag
(For internal use only.)
m_M
int tabprm::m_M
(For internal use only.)
m_N
int tabprm::m_N
(For internal use only.)

Error message handling.

```
#include <wcserr.h>
```

Data Fields

- · int status
- int line_no
- · const char * function
- const char * file
- char * msg

5.14.1 Detailed Description

Error message handling.

The **wcserr** struct contains the numeric error code, a textual description of the error, and information about the function, source file, and line number where the error was generated.

5.14.2 Field Documentation

status

```
int wcserr::status
```

Numeric status code associated with the error, the meaning of which depends on the function that generated it. See the documentation for the particular function.

line_no

```
int wcserr::line_no
```

Line number where the error occurred as given by the __LINE__ preprocessor macro.

const char *function Name of the function where the error occurred.

const char *file Name of the source file where the error occurred as given by the __FILE__ preprocessor macro.

function

```
const char* wcserr::function
```

file

```
const char* wcserr::file
```

msg

```
char * wcserr::msg
```

Informative error message.

5.15.1 Detailed Description

Coordinate transformation parameters.

The **wcsprm** struct contains information required to transform world coordinates. It consists of certain members that must be set by the user (*given*) and others that are set by the WCSLIB routines (*returned*). While the addresses of the arrays themselves may be set by wcsinit() if it (optionally) allocates memory, their contents must be set by the

Some parameters that are given are not actually required for transforming coordinates. These are described as "auxiliary"; the struct simply provides a place to store them, though they may be used by wcshdo() in constructing a FITS header from a wcsprm struct. Some of the returned values are supplied for informational purposes and others are for internal use only as indicated.

In practice, it is expected that a WCS parser would scan the FITS header to determine the number of coordinate axes. It would then use wcsinit() to allocate memory for arrays in the wcsprm struct and set default values. Then as it reread the header and identified each WCS keyrecord it would load the value into the relevant wcsprm array element. This is essentially what wcspih() does - refer to the prologue of wcshdr.h. As the final step, wcsset() is invoked, either directly or indirectly, to set the derived members of the wcsprm struct. wcsset() strips off trailing blanks in all string members and null-fills the character array.

5.15.2 Field Documentation

flag

```
int wcsprm::flag
```

(Given and returned) This flag must be set to zero (or 1, see wcsset()) whenever any of the following wcsprm members are set or changed:

- wcsprm::naxis (q.v., not normally set by the user),
- · wcsprm::crpix,
- · wcsprm::pc,
- · wcsprm::cdelt,
- · wcsprm::crval,
- · wcsprm::cunit,
- wcsprm::ctype,
- · wcsprm::lonpole,
- · wcsprm::latpole,
- wcsprm::restfrq,
- · wcsprm::restwav,
- · wcsprm::npv,
- wcsprm::pv,
- wcsprm::nps,
- wcsprm::ps,
- wcsprm::cd,
- · wcsprm::crota,
- · wcsprm::altlin,
- · wcsprm::ntab,
- · wcsprm::nwtb,
- · wcsprm::tab,
- · wcsprm::wtb.

This signals the initialization routine, wcsset(), to recompute the returned members of the linprm, celprm, spcprm, and tabprm structs. wcsset() will reset flag to indicate that this has been done.

PLEASE NOTE: flag should be set to -1 when wcsinit() is called for the first time for a particular wcsprm struct in order to initialize memory management. It must ONLY be used on the first initialization otherwise memory leaks may result.

naxis

```
int wcsprm::naxis
```

(Given or returned) Number of pixel and world coordinate elements.

If wcsinit() is used to initialize the linprm struct (as would normally be the case) then it will set naxis from the value passed to it as a function argument. The user should not subsequently modify it.

crpix

```
double * wcsprm::crpix
```

(Given) Address of the first element of an array of double containing the coordinate reference pixel, CRPIX ja.

рс

```
double * wcsprm::pc
```

(*Given*) Address of the first element of the **PC**i_ja (pixel coordinate) transformation matrix. The expected order is struct wcsprm wcs;
wcs.pc = {PC1_1, PC1_2, PC2_1, PC2_2};

This may be constructed conveniently from a 2-D array via

which is equivalent to

```
double m[2][2];
m[0][0] = PC1_1;
m[0][1] = PC1_2;
m[1][0] = PC2_1;
m[1][1] = PC2_2;
```

The storage order for this 2-D array is the same as for the 1-D array, whence $wcs.pc = \star m$;

would be legitimate.

cdelt

```
double * wcsprm::cdelt
```

(Given) Address of the first element of an array of double containing the coordinate increments, CDELTia.

crval

```
double * wcsprm::crval
```

(Given) Address of the first element of an array of double containing the coordinate reference values, CRVALia.

cunit

wcsprm::cunit

(*Given*) Address of the first element of an array of char[72] containing the **CUNIT**ia keyvalues which define the units of measurement of the **CRVAL**ia, **CDELT**ia, and **CD**i_ja keywords.

As **CUNIT**ia is an optional header keyword, cunit[][72] may be left blank but otherwise is expected to contain a standard units specification as defined by WCS Paper I. Utility function wcsutrn(), described in wcsunits.h, is available to translate commonly used non-standard units specifications but this must be done as a separate step before invoking wcsset().

For celestial axes, if cunit[][72] is not blank, wcsset() uses wcsunits() to parse it and scale cdelt[], crval[], and cd[][*] to degrees. It then resets cunit[][72] to "deg".

For spectral axes, if cunit[][72] is not blank, wcsset() uses wcsunits() to parse it and scale cdelt[], crval[], and cd[][*] to SI units. It then resets cunit[][72] accordingly.

wcsset() ignores cunit[][72] for other coordinate types; cunit[][72] may be used to label coordinate values.

These variables accomodate the longest allowed string-valued FITS keyword, being limited to 68 characters, plus the null-terminating character.

ctype

wcsprm::ctype

(Given) Address of the first element of an array of char[72] containing the coordinate axis types, CTYPEia.

The ctype[][72] keyword values must be in upper case and there must be zero or one pair of matched celestial axis types, and zero or one spectral axis. The ctype[][72] strings should be padded with blanks on the right and null-terminated so that they are at least eight characters in length.

These variables accomodate the longest allowed string-valued FITS keyword, being limited to 68 characters, plus the null-terminating character.

Ionpole

double wcsprm::lonpole

(Given and returned) The native longitude of the celestial pole, ϕ_p , given by **LONPOLE**a [deg] or by **PVi_2a** [deg] attached to the longitude axis which takes precedence if defined, and ...

latpole

double wcsprm::latpole

(Given and returned) ... the native latitude of the celestial pole, θ_p , given by **LATPOLE**a [deg] or by **PVi_3a** [deg] attached to the longitude axis which takes precedence if defined.

lonpole and latpole may be left to default to values set by wcsinit() (see celprm::ref), but in any case they will be reset by wcsset() to the values actually used. Note therefore that if the wcsprm struct is reused without resetting them, whether directly or via wcsinit(), they will no longer have their default values.

restfrq

```
double wcsprm::restfrq
```

(Given) The rest frequency [Hz], and/or ...

restwav

```
double wcsprm::restwav
```

(Given) ... the rest wavelength in vacuo [m], only one of which need be given, the other should be set to zero.

npv

```
int wcsprm::npv
```

(Given) The number of entries in the wcsprm::pv[] array.

npvmax

```
int wcsprm::npvmax
```

(Given or returned) The length of the wcsprm::pv[] array.

npvmax will be set by wcsinit() if it allocates memory for wcsprm::pv[], otherwise it must be set by the user. See also wcsnpv().

рν

```
struct pvcard * wcsprm::pv
```

(Given) Address of the first element of an array of length npvmax of pvcard structs.

As a FITS header parser encounters each **PV**i_ma keyword it should load it into a pvcard struct in the array and increment npv. wcsset() interprets these as required.

Note that, if they were not given, wcsset() resets the entries for PVi_1a, PVi_2a, PVi_3a, and PVi_4a for longitude axis i to match phi_0 and theta_0 (the native longitude and latitude of the reference point), LONPOLE a and LATPOLE a respectively.

nps

```
int wcsprm::nps
```

(Given) The number of entries in the wcsprm::ps[] array.

npsmax

```
int wcsprm::npsmax
```

(Given or returned) The length of the wcsprm::ps[] array.

npsmax will be set by wcsinit() if it allocates memory for wcsprm::ps[], otherwise it must be set by the user. See also wcsnps().

ps

```
struct pscard * wcsprm::ps
```

(Given) Address of the first element of an array of length npsmax of pscard structs.

As a FITS header parser encounters each **PS**i_ma keyword it should load it into a pscard struct in the array and increment nps. wcsset() interprets these as required (currently no **PS**i_ma keyvalues are recognized).

cd

```
double * wcsprm::cd
```

(*Given*) For historical compatibility, the **wcsprm** struct supports two alternate specifications of the linear transformation matrix, those associated with the \mathbf{CD}_{ja} keywords, and ...

crota

```
double * wcsprm::crota
```

(*Given*) ... those associated with the **CROTA**i keywords. Although these may not formally co-exist with **PC**i_ja, the approach taken here is simply to ignore them if given in conjunction with **PC**i_ja.

altlin

```
int wcsprm::altlin
```

(*Given*) altlin is a bit flag that denotes which of the **PC**i_ja, **CD**i_ja and **CROTA**i keywords are present in the header:

- Bit 0: PCi_ja is present.
- Bit 1: CDi_ja is present.

Matrix elements in the IRAF convention are equivalent to the product $\mathtt{CDi_ja} = \mathtt{CDELTia} * \mathtt{PCi_ja}$, but the defaults differ from that of the $\mathtt{PCi_ja}$ matrix. If one or more $\mathtt{CDi_ja}$ keywords are present then all unspecified $\mathtt{CDi_ja}$ default to zero. If no $\mathtt{CDi_ja}$ (or \mathtt{CROTAi}) keywords are present, then the header is assumed to be in $\mathtt{PCi_ja}$ form whether or not any $\mathtt{PCi_ja}$ keywords are present since this results in an interpretation of $\mathtt{CDELTia}$ consistent with the original FITS specification.

While CDi_ja may not formally co-exist with PCi_ja, it may co-exist with CDELTia and CROTAi which are to be ignored.

• Bit 2: CROTAi is present.

In the AIPS convention, **CROTA**i may only be associated with the latitude axis of a celestial axis pair. It specifies a rotation in the image plane that is applied AFTER the **CDELT**ia; any other **CROTA**i keywords are ignored.

CROTAi may not formally co-exist with **PC**i_ja.

CROTAi and CDELTia may formally co-exist with CDi_ja but if so are to be ignored.

• Bit 3: PCi_ja + CDELTia was derived from CDi_ja by wcspcx().

This bit is set by wcspcx() when it derives PCi_ja and CDELTia from CDi_ja via an orthonormal decomposition. In particular, it signals wcsset() not to replace PCi_ja by a copy of CDi_ja with CDELTia set to unity.

CDi_ja and CROTAi keywords, if found, are to be stored in the wcsprm::cd and wcsprm::crota arrays which are dimensioned similarly to wcsprm::pc and wcsprm::cdelt. FITS header parsers should use the following procedure:

- Whenever a PCi_ja keyword is encountered:
 altlin |= 1;
- Whenever a CDi_ja keyword is encountered:
 altlin |= 2;
- Whenever a CROTAi keyword is encountered:
 altlin |= 4;

If none of these bits are set the PCi_ja representation results, i.e. wcsprm::pc and wcsprm::cdelt will be used as given.

These alternate specifications of the linear transformation matrix are translated immediately to **PC**i_ja by wcsset() and are invisible to the lower-level WCSLIB routines. In particular, unless bit 3 is also set, wcsset() resets wcsprm::cdelt to unity if **CD**i_ja is present (and no **PC**i_ja).

If CROTAi are present but none is associated with the latitude axis (and no PCi_ja or CDi_ja), then wcsset() reverts to a unity PCi_ja matrix.

velref

```
int wcsprm::velref
```

(Given) AIPS velocity code VELREF, refer to spcaips().

It is not necessary to reset the wcsprm struct (via wcsset()) when wcsprm::velref is changed.

alt

```
char wcsprm::alt
```

(Given, auxiliary) Character code for alternate coordinate descriptions (i.e. the 'a' in keyword names such as CTYPEia). This is blank for the primary coordinate description, or one of the 26 upper-case letters, A-Z.

An array of four characters is provided for alignment purposes, only the first is used.

It is not necessary to reset the wcsprm struct (via wcsset()) when wcsprm::alt is changed.

colnum

```
int wcsprm::colnum
```

(Given, auxiliary) Where the coordinate representation is associated with an image-array column in a FITS binary table, this variable may be used to record the relevant column number.

It should be set to zero for an image header or pixel list.

It is not necessary to reset the wcsprm struct (via wcsset()) when wcsprm::colnum is changed.

colax

```
int * wcsprm::colax
```

(Given, auxiliary) Address of the first element of an array of int recording the column numbers for each axis in a pixel list.

The array elements should be set to zero for an image header or image array in a binary table.

It is not necessary to reset the wcsprm struct (via wcsset()) when wcsprm::colax is changed.

cname

```
wcsprm::cname
```

(Given, auxiliary) The address of the first element of an array of char[72] containing the coordinate axis names, **CNAME**ia.

These variables accommodate the longest allowed string-valued FITS keyword, being limited to 68 characters, plus the null-terminating character.

It is not necessary to reset the wcsprm struct (via wcsset()) when wcsprm::cname is changed.

crder

```
double * wcsprm::crder
```

(Given, auxiliary) Address of the first element of an array of double recording the random error in the coordinate value, CRDERia.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::crder is changed.

csyer

```
double * wcsprm::csyer
```

(Given, auxiliary) Address of the first element of an array of double recording the systematic error in the coordinate value, CSYERia.

It is not necessary to reset the wcsprm struct (via wcsset()) when wcsprm::csyer is changed.

czphs

```
double * wcsprm::czphs
```

(Given, auxiliary) Address of the first element of an array of double recording the time at the zero point of a phase axis, CZPHSia.

It is not necessary to reset the wcsprm struct (via wcsset()) when wcsprm::czphs is changed.

cperi

```
double * wcsprm::cperi
```

(Given, auxiliary) Address of the first element of an array of double recording the period of a phase axis, CPERlia.

It is not necessary to reset the wcsprm struct (via wcsset()) when wcsprm::cperi is changed.

wcsname

```
char wcsprm::wcsname
```

(Given, auxiliary) The name given to the coordinate representation, **WCSNAME**a. This variable accommodates the longest allowed string-valued FITS keyword, being limited to 68 characters, plus the null-terminating character.

It is not necessary to reset the wcsprm struct (via wcsset()) when wcsprm::wcsname is changed.

timesys

```
char wcsprm::timesys
```

(Given, auxiliary) **TIMESYS** keyvalue, being the time scale (UTC, TAI, etc.) in which all other time-related auxiliary header values are recorded. Also defines the time scale for an image axis with **CTYPE**ia set to 'TIME'.

It is not necessary to reset the wcsprm struct (via wcsset()) when wcsprm::timesys is changed.

trefpos

```
char wcsprm::trefpos
```

(Given, auxiliary) TREFPOS keyvalue, being the location in space where the recorded time is valid.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::trefpos is changed.

trefdir

```
char wcsprm::trefdir
```

(Given, auxiliary) TREFDIR keyvalue, being the reference direction used in calculating a pathlength delay.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::trefdir is changed.

plephem

char wcsprm::plephem

(Given, auxiliary) PLEPHEM keyvalue, being the Solar System ephemeris used for calculating a pathlength delay.

It is not necessary to reset the wcsprm struct (via wcsset()) when wcsprm::plephem is changed.

timeunit

char wcsprm::timeunit

(Given, auxiliary) **TIMEUNIT** keyvalue, being the time units in which the following header values are expressed: **TSTART**, **TSTOP**, **TIMEOFFS**, **TIMSYER**, **TIMRDER**, **TIMEDEL**. It also provides the default value for **CUNIT**ia for time axes.

It is not necessary to reset the wcsprm struct (via wcsset()) when wcsprm::timeunit is changed.

dateref

char wcsprm::dateref

(Given, auxiliary) **DATEREF** keyvalue, being the date of a reference epoch relative to which other time measurements refer.

It is not necessary to reset the wcsprm struct (via wcsset()) when wcsprm::dateref is changed.

mjdref

double wcsprm::mjdref

(Given, auxiliary) **MJDREF** keyvalue, equivalent to **DATEREF** expressed as a Modified Julian Date (MJD = JD - 2400000.5). The value is given as the sum of the two-element vector, allowing increased precision.

It is not necessary to reset the wcsprm struct (via wcsset()) when wcsprm::mjdref is changed.

timeoffs

double wcsprm::timeoffs

(Given, auxiliary) **TIMEOFFS** keyvalue, being a time offset, which may be used, for example, to provide a uniform clock correction for times referenced to **DATEREF**.

It is not necessary to reset the wcsprm struct (via wcsset()) when wcsprm::timeoffs is changed.

dateobs

char wcsprm::dateobs

(Given, auxiliary) **DATE-OBS** keyvalue, being the date at the start of the observation unless otherwise explained in the **DATE-OBS** keycomment, in ISO format, *yyyy-mm-dd***T***hh:mm:ss*.

It is not necessary to reset the wcsprm struct (via wcsset()) when wcsprm::dateobs is changed.

datebeg

char wcsprm::datebeg

(Given, auxiliary) **DATE-BEG** keyvalue, being the date at the start of the observation in ISO format, *yyyy-mm-dd***T**hh:mm:ss.

It is not necessary to reset the wcsprm struct (via wcsset()) when wcsprm::datebeg is changed.

dateavg

char wcsprm::dateavg

(Given, auxiliary) **DATE-AVG** keyvalue, being the date at a representative mid-point of the observation in ISO format, *yyyy-mm-dd***T***hh:mm:ss*.

It is not necessary to reset the wcsprm struct (via wcsset()) when wcsprm::dateavg is changed.

dateend

char wcsprm::dateend

(Given, auxiliary) **DATE-END** keyvalue, baing the date at the end of the observation in ISO format, *yyyy-mm-dd***T**hh:mm:ss.

It is not necessary to reset the wcsprm struct (via wcsset()) when wcsprm::dateend is changed.

mjdobs

double wcsprm::mjdobs

(Given, auxiliary) **MJD-OBS** keyvalue, equivalent to **DATE-OBS** expressed as a Modified Julian Date (MJD = JD - 2400000.5).

It is not necessary to reset the wcsprm struct (via wcsset()) when wcsprm::mjdobs is changed.

mjdbeg

double wcsprm::mjdbeg

(Given, auxiliary) **MJD-BEG** keyvalue, equivalent to **DATE-BEG** expressed as a Modified Julian Date (MJD = JD - 2400000.5).

It is not necessary to reset the wcsprm struct (via wcsset()) when wcsprm::mjdbeg is changed.

mjdavg

double wcsprm::mjdavg

(Given, auxiliary) MJD-AVG keyvalue, equivalent to DATE-AVG expressed as a Modified Julian Date (MJD = JD - 2400000.5).

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::mjdavg is changed.

mjdend

double wcsprm::mjdend

(Given, auxiliary) **MJD-END** keyvalue, equivalent to **DATE-END** expressed as a Modified Julian Date (MJD = JD - 2400000.5).

It is not necessary to reset the wcsprm struct (via wcsset()) when wcsprm::mjdend is changed.

jepoch

double wcsprm::jepoch

(Given, auxiliary) JEPOCH keyvalue, equivalent to DATE-OBS expressed as a Julian epoch.

It is not necessary to reset the wcsprm struct (via wcsset()) when wcsprm::jepoch is changed.

bepoch

double wcsprm::bepoch

(Given, auxiliary) BEPOCH keyvalue, equivalent to DATE-OBS expressed as a Besselian epoch

It is not necessary to reset the wcsprm struct (via wcsset()) when wcsprm::bepoch is changed.

tstart

double wcsprm::tstart

(Given, auxiliary) **TSTART** keyvalue, equivalent to **DATE-BEG** expressed as a time in units of **TIMEUNIT** relative to **DATEREF+TIMEOFFS**.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::tstart is changed.

tstop

double wcsprm::tstop

(Given, auxiliary) **TSTOP** keyvalue, equivalent to **DATE-END** expressed as a time in units of **TIMEUNIT** relative to **DATEREF+TIMEOFFS**.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::tstop is changed.

xposure

double wcsprm::xposure

(Given, auxiliary) XPOSURE keyvalue, being the effective exposure time in units of TIMEUNIT.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::xposure is changed.

telapse

double wcsprm::telapse

(Given, auxiliary) **TELAPSE** keyvalue, equivalent to the elapsed time between **DATE-BEG** and **DATE-END**, in units of **TIMEUNIT**.

It is not necessary to reset the wcsprm struct (via wcsset()) when wcsprm::telapse is changed.

timsyer

double wcsprm::timsyer

(Given, auxiliary) TIMSYER keyvalue, being the absolute error of the time values, in units of TIMEUNIT.

It is not necessary to reset the wcsprm struct (via wcsset()) when wcsprm::timsyer is changed.

timrder

double wcsprm::timrder

(Given, auxiliary) **TIMRDER** keyvalue, being the accuracy of time stamps relative to each other, in units of **TIMEUNIT**.

It is not necessary to reset the wcsprm struct (via wcsset()) when wcsprm::timrder is changed.

timedel

double wcsprm::timedel

(Given, auxiliary) TIMEDEL keyvalue, being the resolution of the time stamps.

It is not necessary to reset the wcsprm struct (via wcsset()) when wcsprm::timedel is changed.

timepixr

double wcsprm::timepixr

(Given, auxiliary) **TIMEPIXR** keyvalue, being the relative position of the time stamps in binned time intervals, a value between 0.0 and 1.0.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::timepixr is changed.

obsgeo

double wcsprm::obsgeo

(Given, auxiliary) Location of the observer in a standard terrestrial reference frame. The first three give ITRS Cartesian coordinates OBSGEO-X [m], OBSGEO-Y [m], OBSGEO-Z [m], and the second three give OBSGEO-L [deg], OBSGEO-B [deg], OBSGEO-H [m], which are related through a standard transformation.

It is not necessary to reset the wcsprm struct (via wcsset()) when wcsprm::obsgeo is changed.

obsorbit

char wcsprm::obsorbit

(Given, auxiliary) **OBSORBIT** keyvalue, being the URI, URL, or name of an orbit ephemeris file giving spacecraft coordinates relating to **TREFPOS**.

It is not necessary to reset the wcsprm struct (via wcsset()) when wcsprm::obsorbit is changed.

radesys

char wcsprm::radesys

(Given, auxiliary) The equatorial or ecliptic coordinate system type, RADESYSa.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::radesys is changed.

equinox

double wcsprm::equinox

(Given, auxiliary) The equinox associated with dynamical equatorial or ecliptic coordinate systems, **EQUINOX**a (or **EPOCH** in older headers). Not applicable to ICRS equatorial or ecliptic coordinates.

It is not necessary to reset the wcsprm struct (via wcsset()) when wcsprm::equinox is changed.

specsys

char wcsprm::specsys

(Given, auxiliary) Spectral reference frame (standard of rest), SPECSYSa.

It is not necessary to reset the **wcsprm** struct (via wcsset()) when wcsprm::specsys is changed.

ssysobs

char wcsprm::ssysobs

(Given, auxiliary) The spectral reference frame in which there is no differential variation in the spectral coordinate across the field-of-view, SSYSOBSa.

It is not necessary to reset the wcsprm struct (via wcsset()) when wcsprm::ssysobs is changed.

velosys

double wcsprm::velosys

(Given, auxiliary) The relative radial velocity [m/s] between the observer and the selected standard of rest in the direction of the celestial reference coordinate, **VELOSYS**a.

It is not necessary to reset the wcsprm struct (via wcsset()) when wcsprm::velosys is changed.

zsource

double wcsprm::zsource

(Given, auxiliary) The redshift, **ZSOURCE**a, of the source.

It is not necessary to reset the wcsprm struct (via wcsset()) when wcsprm::zsource is changed.

ssyssrc

char wcsprm::ssyssrc

(Given, auxiliary) The spectral reference frame (standard of rest), SSYSSRCa, in which wcsprm::zsource was measured.

It is not necessary to reset the wcsprm struct (via wcsset()) when wcsprm::ssyssrc is changed.

velangl

double wcsprm::velangl

(Given, auxiliary) The angle [deg] that should be used to decompose an observed velocity into radial and transverse components.

It is not necessary to reset the wcsprm struct (via wcsset()) when wcsprm::velangl is changed.

aux

```
struct auxprm * wcsprm::aux
```

(Given, auxiliary) This struct holds auxiliary coordinate system information of a specialist nature. While these parameters may be widely recognized within particular fields of astronomy, they differ from the above auxiliary parameters in not being defined by any of the FITS WCS standards. Collecting them together in a separate struct that is allocated only when required helps to control bloat in the size of the **wcsprm** struct.

ntab

int wcsprm::ntab

(Given) See wcsprm::tab.

nwtb

int wcsprm::nwtb

(Given) See wcsprm::wtb.

tab

```
struct tabprm * wcsprm::tab
```

(*Given*) Address of the first element of an array of ntab tabprm structs for which memory has been allocated. These are used to store tabular transformation parameters.

Although technically wcsprm::ntab and tab are "given", they will normally be set by invoking wcstab(), whether directly or indirectly.

The tabprm structs contain some members that must be supplied and others that are derived. The information to be supplied comes primarily from arrays stored in one or more FITS binary table extensions. These arrays, referred to here as "wcstab arrays", are themselves located by parameters stored in the FITS image header.

wtb

```
struct wtbarr * wcsprm::wtb
```

(*Given*) Address of the first element of an array of nwtb wtbarr structs for which memory has been allocated. These are used in extracting wcstab arrays from a FITS binary table.

Although technically wcsprm::nwtb and wtb are "given", they will normally be set by invoking wcstab(), whether directly or indirectly.

Ingtyp

```
char wcsprm::lngtyp
```

(Returned) Four-character WCS celestial longitude and ...

lattyp

```
char wcsprm::lattyp
```

(*Returned*) ... latitude axis types. e.g. "RA", "DEC", "GLON", "GLAT", etc. extracted from 'RA-', 'DEC-', 'GLON', 'GLAT', etc. in the first four characters of CTYPEia but with trailing dashes removed. (Declared as char[8] for alignment reasons.)

Ing

```
int wcsprm::lng
```

(Returned) Index for the longitude coordinate, and ...

lat

```
int wcsprm::lat
```

 $(\textit{Returned}) \dots$ index for the latitude coordinate, and \dots

spec

```
int wcsprm::spec
```

(Returned) ... index for the spectral coordinate, and ...

time

```
int wcsprm::time
```

(*Returned*) ... index for the time coordinate in the imgcrd[][] and world[][] arrays in the API of wcsp2s(), wcss2p() and wcsmix().

These may also serve as indices into the pixcrd[[[] array provided that the PCi_ja matrix does not transpose axes.

cubeface

```
int wcsprm::cubeface
```

(*Returned*) Index into the pixcrd[][] array for the **CUBEFACE** axis. This is used for quadcube projections where the cube faces are stored on a separate axis (see wcs.h).

chksum

```
int wcsprm::chksum
```

(*Returned*) Checksum of keyvalues provided (see wcsprm::flag). Used by wcsenq() to validate the self-consistency of the struct. Note that the checksum incorporates addresses and is therefore highly specific to the instance of the wcsprm struct.

types

```
int * wcsprm::types
```

(Returned) Address of the first element of an array of int containing a four-digit type code for each axis.

- First digit (i.e. 1000s):
 - 0: Non-specific coordinate type.
 - 1: Stokes coordinate.
 - 2: Celestial coordinate (including CUBEFACE).
 - 3: Spectral coordinate.
 - 4: Time coordinate.
- · Second digit (i.e. 100s):
 - 0: Linear axis.
 - 1: Quantized axis (STOKES, CUBEFACE).

- 2: Non-linear celestial axis.
- 3: Non-linear spectral axis.
- 4: Logarithmic axis.
- 5: Tabular axis.
- Third digit (i.e. 10s):
 - 0: Group number, e.g. lookup table number, being an index into the tabprm array (see above).
- The fourth digit is used as a qualifier depending on the axis type.
 - For celestial axes:
 - * 0: Longitude coordinate.
 - * 1: Latitude coordinate.
 - * 2: CUBEFACE number.
 - For lookup tables: the axis number in a multidimensional table.

CTYPEia in "4-3" form with unrecognized algorithm code will have its type set to -1 and generate an error.

lin

```
struct linprm wcsprm::lin
```

(Returned) Linear transformation parameters (usage is described in the prologue to lin.h).

cel

```
struct celprm wcsprm::cel
```

(Returned) Celestial transformation parameters (usage is described in the prologue to cel.h).

spc

```
struct spcprm wcsprm::spc
```

(Returned) Spectral transformation parameters (usage is described in the prologue to spc.h).

err

```
struct wcserr * wcsprm::err
```

(*Returned*) If enabled, when an error status is returned, this struct contains detailed information about the error, see wcserr_enable().

m_flag

```
int wcsprm::m_flag
```

(For internal use only.)

```
m_naxis

5.16 wtbarr Struct Reference

(For internal use only.)

Extraction of coordinate lookup tables from BINTABLE.

```
#include <getwcstab.h>
```

Data Fields

- int i
- int m
- int kind
- char extnam [72]
- · int extver
- int extlev
- char ttype [72]
- long row
- int ndim
- int * dimlen
- double ** arrayp

5.16.1 Detailed Description

Extraction of coordinate lookup tables from BINTABLE.

Function wcstab(), which is invoked automatically by wcspih(), sets up an array of wtbarr structs to assist in extracting coordinate lookup tables from a binary table extension (BINTABLE) and copying them into the tabprm structs stored in wcsprm. Refer to the usage notes for wcspih() and wcstab() in wcshdr.h, and also the prologue to tab.h.

For C++ usage, because of a name space conflict with the **wtbarr** typedef defined in CFITSIO header fitsio.h, the **wtbarr** struct is renamed to **wtbarr_s** by preprocessor macro substitution with scope limited to **wtbarr.h** itself, and similarly in wcs.h.

5.16.2 Field Documentation

```
int wtbarr::i
```

(Given) Image axis number.

m

i

int wtbarr::m

(Given) westab array axis number for index vectors.

kind

int wtbarr::kind

(Given) Character identifying the wcstab array type:

- · c: coordinate array,
- i: index vector.

extnam

char wtbarr::extnam

(Given) **EXTNAME** identifying the binary table extension.

extver

int wtbarr::extver

(Given) EXTVER identifying the binary table extension.

6 File Documentation 93

extlev

```
int wtbarr::extlev
```

(Given) **EXTLEV** identifying the binary table extension.

ttype

```
char wtbarr::ttype
```

(Given) TTYPEn identifying the column of the binary table that contains the westab array.

row

```
long wtbarr::row
```

(Given) Table row number.

ndim

```
int wtbarr::ndim
```

(Given) Expected dimensionality of the wcstab array.

dimlen

```
int * wtbarr::dimlen
```

(*Given*) Address of the first element of an array of int of length ndim into which the wcstab array axis lengths are to be written.

arrayp

```
double ** wtbarr::arrayp
```

(*Given*) Pointer to an array of double which is to be allocated by the user and into which the wcstab array is to be written.

• enum celenq_enum { CELENQ_SET = 2 , CELENQ_BYP = 4 }
```

```
    enum cel_errmsg_enum {
    CELERR_SUCCESS = 0 , CELERR_NULL_POINTER = 1 , CELERR_BAD_PARAM = 2 , CELERR_BAD_COORD_TRANS = 3 ,
    CELERR_ILL_COORD_TRANS = 4 , CELERR_BAD_PIX = 5 , CELERR_BAD_WORLD = 6 }
```

Functions

• int celini (struct celprm *cel)

Default constructor for the celprm struct.

int celfree (struct celprm *cel)

Destructor for the celprm struct.

• int celsize (const struct celprm *cel, int sizes[2])

Compute the size of a celprm struct.

• int celeng (const struct celprm *cel, int enquiry)

enquire about the state of a celprm struct.

int celprt (const struct celprm *cel)

Print routine for the celprm struct.

• int celperr (const struct celprm *cel, const char *prefix)

Print error messages from a celprm struct.

• int celset (struct celprm *cel)

Setup routine for the celprm struct.

• int celx2s (struct celprm *cel, int nx, int ny, int sxy, int sll, const double x[], const double y[], double phi[], double theta[], double lng[], double lat[], int stat[])

Pixel-to-world celestial transformation.

• int cels2x (struct celprm *cel, int nlng, int nlat, int sll, int sxy, const double lng[], const double lat[], double phi[], double theta[], double x[], double y[], int stat[])

World-to-pixel celestial transformation.

    Status return messages.
```

6.1.1 Detailed Description

Routines in this suite implement the part of the FITS World Coordinate System (WCS) standard that deals with celestial coordinates, as described in

```
"Representations of world coordinates in FITS",
Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061 (WCS Paper I)
"Representations of celestial coordinates in FITS",
Calabretta, M.R., & Greisen, E.W. 2002, A&A, 395, 1077 (WCS Paper II)
```

These routines define methods to be used for computing celestial world coordinates from intermediate world coordinates (a linear transformation of image pixel coordinates), and vice versa. They are based on the celprm struct which contains all information needed for the computations. This struct contains some elements that must be set by the user, and others that are maintained by these routines, somewhat like a C++ class but with no encapsulation.

Routine celini() is provided to initialize the celprm struct with default values, celfree() reclaims any memory that may have been allocated to store an error message, celsize() computes its total size including allocated memory, celeng() returns information about the state of the struct, and celprt() prints its contents.

celperr() prints the error message(s), if any, stored in a celprm struct and the priprm struct that it contains.

A setup routine, celset(), computes intermediate values in the celprm struct from parameters in it that were supplied by the user. The struct always needs to be set up by celset() but it need not be called explicitly - refer to the explanation of celprm::flag.

celx2s() and cels2x() implement the WCS celestial coordinate transformations. In fact, they are high level driver routines for the lower level spherical coordinate rotation and projection routines described in sph.h and prj.h.

6.1.2 Macro Definition Documentation

CELLEN

```
#define CELLEN (sizeof(struct celprm)/sizeof(int))
```

Size of the celprm struct in int units.

Size of the celprm struct in *int* units, used by the Fortran wrappers.

celini_errmsg

```
#define celini_errmsg cel_errmsg
```

Deprecated.

Deprecated Added for backwards compatibility, use cel_errmsg directly now instead.

celprt_errmsg

```
#define celprt_errmsg cel_errmsg
```

Deprecated.

Deprecated Added for backwards compatibility, use cel_errmsg directly now instead.

celset_errmsg

```
#define celset_errmsg cel_errmsg
```

Deprecated.

Deprecated Added for backwards compatibility, use cel_errmsg directly now instead.

celx2s_errmsg

```
#define celx2s_errmsg cel_errmsg
```

Deprecated.

Deprecated Added for backwards compatibility, use cel_errmsg directly now instead.

cels2x_errmsg

```
#define cels2x_errmsg cel_errmsg
```

Deprecated.

Deprecated Added for backwards compatibility, use cel_errmsg directly now instead.

6.1.3 Enumeration Type Documentation

celenq_enum

enum celenq_enum

CELERR_NULL_POINTER	
CELERR_BAD_PARAM	
CELERR_BAD_COORD_TRANS	
CELERR_ILL_COORD_TRANS	
CELERR_BAD_PIX	
CELERR_BAD_WORLD	

6.1.4 Function Documentation

celini()

```
int celini ( {\tt struct\ celprm\ *\ cel\ )}
```

Default constructor for the celprm struct.

celini() sets all members of a celprm struct to default values. It should be used to initialize every celprm struct.

PLEASE NOTE: If the celprm struct has already been initialized, then before reinitializing, it celfree() should be used to free any memory that may have been allocated to store an error message. A memory leak may otherwise result.

Parameters

out	cel	Celestial transformation parameters.

Returns

Status return value:

- 0: Success.
- 1: Null celprm pointer passed.

celfree()

Destructor for the celprm struct.

celfree() frees any memory that may have been allocated to store an error message in the celprm struct.

Parameters

in cel Celestial transformation parameters.	
---	--

Returns

Status return value:

- 0: Success.
- 1: Null celprm pointer passed.

celsize()

```
int celsize (  {\rm const\ struct\ celprm\ *\ cel},  int sizes[2] )
```

Compute the size of a celprm struct.

celsize() computes the full size of a celprm struct, including allocated memory.

Parameters

in	cel	Celestial transformation parameters.
		If NULL, the base size of the struct and the allocated size are both set to zero.
out	sizes	The first element is the base size of the struct as returned by sizeof(struct celprm). The second element is the total allocated size, in bytes. This figure includes memory allocated for the constituent struct, celprm::err. It is not an error for the struct not to have been set up via celset().

Returns

Status return value:

• 0: Success.

celenq()

```
int celenq ( \label{eq:const_struct_celprm} \mbox{const struct celprm } * \mbox{ cel}, \mbox{int } \mbox{enquiry } \mbox{)}
```

enquire about the state of a celprm struct.

celenq() may be used to obtain information about the state of a celprm struct. The function returns a true/false answer for the enquiry asked.

Parameters

in	cel	Celestial transformation parameters.	
in	enquiry	Enquiry according to the following parameters:	
		CELENQ_SET: the struct has been set up by celset() May 14 20 CELENQ_BYP: the struct is in bypass mode (see celset()).	024 02:34:19 for WCSLIB by Doxygen

6.1 cel.h File Reference 99

Returns

Enquiry result:

- 0: No.
- 1: Yes.

celprt()

```
int celprt ( {\tt const\ struct\ celprm\ *\ cel}\ )
```

Print routine for the celprm struct.

celprt() prints the contents of a celprm struct using wcsprintf(). Mainly intended for diagnostic purposes.

Parameters

in	cel	Celestial transformation parameters.	1
----	-----	--------------------------------------	---

Returns

Status return value:

- 0: Success.
- 1: Null celprm pointer passed.

celperr()

Print error messages from a celprm struct.

celperr() prints the error message(s), if any, stored in a celprm struct and the prjprm struct that it contains. If there are no errors then nothing is printed. It uses wcserr_prt(), q.v.

Parameters

in	cel	Coordinate transformation parameters.
in	prefix	If non-NULL, each output line will be prefixed with this string.

Returns

Status return value:

- 0: Success.
- 1: Null celprm pointer passed.

celset()

```
int celset ( {\tt struct\ celprm\ *\ cel}\ )
```

Setup routine for the celprm struct.

celset() sets up a celprm struct according to information supplied within it.

Note that this routine need not be called directly; it will be invoked by celx2s() and cels2x() if celprm::flag is anything other than a predefined magic value.

celset() normally operates regardless of the value of celprm::flag; i.e. even if a struct was previously set up it will be reset unconditionally. However, a celprm struct may be put into "bypass" mode by invoking **celset**() initially with celprm::flag == 1 (rather than 0). **celset**() will return immediately if invoked on a struct in that state. To take a struct out of bypass mode, simply reset celprm::flag to zero. See also celeng().

Parameters

in,out	cel	Celestial transformation parameters.	
--------	-----	--------------------------------------	--

Returns

Status return value:

- 0: Success.
- 1: Null celprm pointer passed.
- 2: Invalid projection parameters.
- 3: Invalid coordinate transformation parameters.
- 4: Ill-conditioned coordinate transformation parameters.

For returns > 1, a detailed error message is set in celprm::err if enabled, see wcserr_enable().

celx2s()

Pixel-to-world celestial transformation.

celx2s() transforms (x,y) coordinates in the plane of projection to celestial coordinates (α,δ) .

6.1 cel.h File Reference 101

Parameters

in,out	cel	Celestial transformation parameters.
in	nx,ny	Vector lengths.
in	sxy,sll	Vector strides.
in	x,y	Projected coordinates in pseudo "degrees".
out	phi,theta	Longitude and latitude (ϕ,θ) in the native coordinate system of the projection [deg].
out	Ing,lat	Celestial longitude and latitude (α, δ) of the projected point [deg].
out	stat	Status return value for each vector element:
		• 0: Success.
		• 1: Invalid value of (x,y) .

Returns

Status return value:

- 0: Success.
- 1: Null celprm pointer passed.
- 2: Invalid projection parameters.
- 3: Invalid coordinate transformation parameters.
- · 4: Ill-conditioned coordinate transformation parameters.
- 5: One or more of the (x,y) coordinates were invalid, as indicated by the stat vector.

For returns > 1, a detailed error message is set in celprm::err if enabled, see wcserr_enable().

cels2x()

World-to-pixel celestial transformation.

cels2x() transforms celestial coordinates (α, δ) to (x, y) coordinates in the plane of projection.

Parameters

in,out	cel	Celestial transformation parameters.
in	nlng,nlat	Vector lengths.
in	sll,sxy	Vector strides.

Parameters

in	Ing,lat	Celestial longitude and latitude (α,δ) of the projected point [deg].
out	$ phi,theta $ Longitude and latitude (ϕ,θ) in the native coordinate system of the projection [deg].	
out	x,y	Projected coordinates in pseudo "degrees".
out	stat	Status return value for each vector element:
		• 0: Success. • 1: Invalid value of (α, δ) .

Returns

Status return value:

- 0: Success.
- 1: Null celprm pointer passed.
- · 2: Invalid projection parameters.
- 3: Invalid coordinate transformation parameters.
- · 4: Ill-conditioned coordinate transformation parameters.
- 6: One or more of the (α, δ) coordinates were invalid, as indicated by the stat vector.

For returns > 1, a detailed error message is set in celprm::err if enabled, see wcserr_enable().

6.1.5 Variable Documentation

cel_errmsg

```
const char * cel_errmsg[] [extern]
```

Status return messages.

Status messages to match the status value returned from each function.

00186 \star celset() - Setup routine for the celprm struct
00187 *
00188 \star celset() sets up a celprm struct according to information supplied within
00189 * it.
00190 *
00191 \star Note that this routine need not be called directly; it will be invoked by
00192 \star celx2s() and cels2x() if celprm::flag is anything other than a predefined
00193 * magic value.
00194
00195 \star celset() normally operates regardless of the value of celprm::flag; i.e.
00196 * even if a struct was previously set up it will be reset unconditionally.
```

6.2 cel.h 105

```
00197 * However, a celprm struct may be put into "bypass" mode by invoking celset()
00198 * initially with celprm::flag == 1 (rather than 0). celset() will return 00199 * immediately if invoked on a struct in that state. To take a struct out of
00200 \star bypass mode, simply reset celprm::flag to zero. See also celenq().
00201 *
00202 * Given and returned:
00203 * cel
                    struct celprm*
00204 *
                                Celestial transformation parameters.
00205 *
00206 * Function return value:
00207 *
                               Status return value:
                     int
00208 *
                                  0: Success.
00209 *
                                  1: Null celprm pointer passed.
00210 *
                                  2: Invalid projection parameters.
00211 *
                                  3: Invalid coordinate transformation parameters.
00212 *
                                  4: Ill-conditioned coordinate transformation
                                     parameters.
00213 *
00214 *
00215
                                For returns > 1, a detailed error message is set in
00216
                                celprm::err if enabled, see wcserr_enable().
00217 *
00218 *
00219 * celx2s() - Pixel-to-world celestial transformation
00220 * -
00221 \star celx2s() transforms (x,y) coordinates in the plane of projection to 00222 \star celestial coordinates (lng,lat).
00223 *
00224 * Given and returned:
00225 *
         cel
                    struct celprm*
00226 *
                                Celestial transformation parameters.
00227 *
00228 * Given:
00229 * nx,ny
                               Vector lengths.
00230 *
00231 *
          sxy,sll int
                               Vector strides.
00232 *
00233 *
         x,y
                     const double[]
00234 *
                               Projected coordinates in pseudo "degrees".
00235 *
00236 * Returned:
00237 *
         phi,theta double[] Longitude and latitude (phi,theta) in the native
00238 *
                               coordinate system of the projection [deg].
00239 *
00240 *
          lng,lat double[] Celestial longitude and latitude (lng,lat) of the
00241 *
                               projected point [deg].
00242 *
00243 *
         stat
                    int[]
                               Status return value for each vector element:
00244 *
                                  0: Success.
00245 *
                                  1: Invalid value of (x,v).
00246 *
00247 * Function return value:
00248 *
                                Status return value:
00249 *
                                  0: Success.
00250 *
                                  1: Null celprm pointer passed.
00251 *
                                  2: Invalid projection parameters.
00252 *
                                  3: Invalid coordinate transformation parameters.
                                  4: Ill-conditioned coordinate transformation
00253 *
00254 *
00255 *
                                  5: One or more of the (x,y) coordinates were
00256 *
                                     invalid, as indicated by the stat vector.
00257 *
00258 *
                                For returns > 1, a detailed error message is set in
00259 *
                                celprm::err if enabled, see wcserr_enable().
00260 *
00261
00262 * cels2x() - World-to-pixel celestial transformation
00263 * -
00264 \star cels2x() transforms celestial coordinates (lng,lat) to (x,y) coordinates in
00265 * the plane of projection.
00266 *
00267 * Given and returned:
00268 * cel
                   struct celprm*
00269 *
                               Celestial transformation parameters.
00270 *
00271 * Given:
00272 *
         nlng, nlat int
                               Vector lengths.
00273 *
00274 *
          sll,sxy int
                               Vector strides.
00275 *
00276 *
          lng,lat const double[]
00277 *
                               Celestial longitude and latitude (lng, lat) of the
00278 *
                               projected point [deg].
00279 *
00280 * Returned:
00281 *
         phi,theta double[] Longitude and latitude (phi,theta) in the native
00282 *
                                coordinate system of the projection [deg].
00283 *
```

```
00284 *
                    double[] Projected coordinates in pseudo "degrees".
         X, V
00285 *
00286 *
          stat
                    int[]
                              Status return value for each vector element:
00287 *
                                 0: Success.
00288 *
                                 1: Invalid value of (lng, lat).
00289 *
00290 * Function return value:
00291 *
                               Status return value:
00292 *
                                 0: Success.
00293 *
                                 1: Null celprm pointer passed.
00294 *
                                 2: Invalid projection parameters.
00295 *
                                 3: Invalid coordinate transformation parameters.
00296 *
                                 4: Ill-conditioned coordinate transformation
00297 *
                                    parameters.
00298 *
                                 6: One or more of the (lng,lat) coordinates were
00299 *
                                    invalid, as indicated by the stat vector.
00300 *
00301 *
                               For returns > 1, a detailed error message is set in
                               celprm::err if enabled, see wcserr_enable().
00302 *
00303
00304 *
00305 \star celprm struct - Celestial transformation parameters
00306 * ---
00307 \star The celprm struct contains information required to transform celestial
00308 \star coordinates. It consists of certain members that must be set by the user
00309 \star ("given") and others that are set by the WCSLIB routines ("returned"). Some
00310 \star of the latter are supplied for informational purposes and others are for
00311 * internal use only.
00312 *
00313 \star Returned celprm struct members must not be modified by the user.
00314 *
00315 *
         int flag
00316 *
            (Given and returned) This flag must be set to zero (or 1, see celset())
00317 *
            whenever any of the following celprm struct members are set or changed:
00318 *
00319 *
              - celprm::offset,
00320 *
              - celprm::phi0,
00321 *
              - celprm::theta0,
00322 *
              - celprm::ref[4],
00323 *
              - celprm::prj:
00324 *
                - prjprm::code,
00325 *
                - prjprm::r0,
00326 *
                - prjprm::pv[],
00327 *
                - prjprm::phi0,
00328 *
                - prjprm::theta0.
00329 *
00330 *
            This signals the initialization routine, celset(), to recompute the
00331 *
            returned members of the celprm struct. celset() will reset flag to
00332 *
            indicate that this has been done.
00333 *
00334 *
         int offset
            (Given) If true (non-zero), an offset will be applied to (x,y) to force (x,y) = (0,0) at the fiducial point, (phi_0,theta_0).
00335 *
00336 *
            Default is 0 (false).
00337 *
00338 *
00339 *
         double phi0
00340 *
            (Given) The native longitude, phi_0 [deg], and ...
00341 *
00342 *
          double theta0
00343 *
            (Given) ... the native latitude, theta_0 [deg], of the fiducial point,
00344 *
            i.e. the point whose celestial coordinates are given in
            celprm::ref[1:2]. If undefined (set to a magic value by prjini()) the
00345 *
00346 *
            initialization routine, celset(), will set this to a projection-specific
00347 *
            default.
00348 *
00349 *
          double ref[4]
00350 *
            (Given) The first pair of values should be set to the celestial
            longitude and latitude of the fiducial point [deg] - typically right
00351 *
00352 *
            ascension and declination. These are given by the CRVALia keywords in
00353 *
            FITS.
00354 *
00355 *
            (Given and returned) The second pair of values are the native longitude,
00356 *
            phi_p [deg], and latitude, theta_p [deg], of the celestial pole (the
00357 *
            latter is the same as the celestial latitude of the native pole,
00358 *
            delta_p) and these are given by the FITS keywords LONPOLEa and LATPOLEa
            (or by PVi_2a and PVi_3a attached to the longitude axis which take
00359 *
00360 *
            precedence if defined).
00361 *
            LONPOLEa defaults to phi_0 (see above) if the celestial latitude of the
00362 *
            fiducial point of the projection is greater than or equal to the native
00363 *
00364 *
            latitude, otherwise phi_0 + 180 [deg]. (This is the condition for the
            celestial latitude to increase in the same direction as the native
00365 *
00366 *
            latitude at the fiducial point.) ref[2] may be set to UNDEFINED (from
00367 *
            wcsmath.h) or 999.0 to indicate that the correct default should be
            substituted.
00368 *
00369 *
00370 *
            theta p, the native latitude of the celestial pole (or equally the
```

6.2 cel.h 107

```
celestial latitude of the native pole, delta_p) is often determined
            uniquely by CRVALia and LONPOLEa in which case LATPOLEa is ignored.
00372 *
00373 *
                     in some circumstances there are two valid solutions for theta_p
            However,
00374 *
            and LATPOLEa is used to choose between them. LATPOLEa is set in ref[3]
00375 *
            and the solution closest to this value is used to reset ref[3]. It is
00376 *
            therefore legitimate, for example, to set ref[3] to +90.0 to choose the
            more northerly solution - the default if the LATPOLEa keyword is omitted
00377 *
00378 *
            from the FITS header. For the special case where the fiducial point of
            the projection is at native latitude zero, its celestial latitude is
00379 *
            zero, and LONPOLEa = +/- 90.0 then the celestial latitude of the native
00380 *
00381 *
            pole is not determined by the first three reference values and LATPOLEa
00382 *
            specifies it completely.
00383 *
00384 *
            The returned value, celprm::latpreq, specifies how LATPOLEa was actually
00385 *
00386 *
00387 *
          struct prjprm prj
00388 *
            (Given and returned) Projection parameters described in the prologue to
00389 *
            prj.h.
00390 *
00391 *
          double euler[5]
00392 *
            (Returned) Euler angles and associated intermediaries derived from the
00393 *
            coordinate reference values. The first three values are the Z-, X-, and
            \mathbf{Z'}\text{-}\mathbf{Euler} angles [deg], and the remaining two are the cosine and sine of
00394 *
00395 *
            the X-Euler angle.
00396 *
00397 *
          int latpreq
00398 *
            (Returned) For informational purposes, this indicates how the LATPOLEa
            keyword was used
00399 *
              - 0: Not required, theta_p (== delta_p) was determined uniquely by the
00400 *
00401 *
                   CRVALia and LONPOLEa keywords.
00402 *
              - 1: Required to select between two valid solutions of theta_p.
00403 *
              - 2: theta_p was specified solely by LATPOLEa.
00404 *
00405 *
          int isolat
            (Returned) True if the spherical rotation preserves the magnitude of the
00406 *
            latitude, which occurs iff the axes of the native and celestial coordinates are coincident. It signals an opportunity to cache
00407 *
00409 *
            intermediate calculations common to all elements in a vector
00410 *
            computation.
00411 *
00412 *
         struct wcserr *err
            (Returned) If enabled, when an error status is returned, this struct
00413 *
00414 *
            contains detailed information about the error, see wcserr_enable().
00415 *
00416 *
          void *padding
00417 *
            (An unused variable inserted for alignment purposes only.)
00418 *
00419 *
00420 * Global variable: const char *cel errmsg[] - Status return messages
00422 * Status messages to match the status value returned from each function.
00423 *

Data Structures

struct dpkey

Store for DP ja and DQia keyvalues.

struct disprm

Distortion parameters.

Macros

- #define DISP2X ARGS
- #define DISX2P_ARGS
- #define DPLEN (sizeof(struct dpkey)/sizeof(int))
- #define DISLEN (sizeof(struct disprm)/sizeof(int))

Enumerations

```
    enum disenq_enum { DISENQ_MEM = 1 , DISENQ_SET = 2 , DISENQ_BYP = 4 }
    enum dis_errmsg_enum {
        DISERR_SUCCESS = 0 , DISERR_NULL_POINTER = 1 , DISERR_MEMORY = 2 , DISERR_BAD_PARAM = 3 ,
        DISERR_DISTORT = 4 , DISERR_DEDISTORT = 5 }
```

Functions

• int disndp (int n)

Memory allocation for DP ja and DQia.

• int dpfill (struct dpkey *dp, const char *keyword, const char *field, int j, int type, int i, double f)

Fill the contents of a dpkey struct.

int dpkeyi (const struct dpkey *dp)

Get the data value in a dpkey struct as int.

double dpkeyd (const struct dpkey *dp)

Get the data value in a dpkey struct as double.

int disini (int alloc, int naxis, struct disprm *dis)

Default constructor for the disprm struct.

• int disinit (int alloc, int naxis, struct disprm *dis, int ndpmax)

Default constructor for the disprm struct.

• int discpy (int alloc, const struct disprm *dissrc, struct disprm *disdst)

Copy routine for the disprm struct.

int disfree (struct disprm *dis)

Destructor for the disprm struct.

• int dissize (const struct disprm *dis, int sizes[2])

Compute the size of a disprm struct.

• int disenq (const struct disprm *dis, int enquiry)

enquire about the state of a disprm struct.

int disprt (const struct disprm *dis)

Print routine for the disprm struct.

int disperr (const struct disprm *dis, const char *prefix)

Print error messages from a disprm struct.

• int dishdo (struct disprm *dis)

write FITS headers using TPD.

int disset (struct disprm *dis)

Setup routine for the disprm struct.

int disp2x (struct disprm *dis, const double rawcrd[], double discrd[])

Apply distortion function.

int disx2p (struct disprm *dis, const double discrd[], double rawcrd[])

Apply de-distortion function.

• int diswarp (struct disprm *dis, const double pixblc[], const double pixtrc[], const double pixsamp[], int *nsamp, double maxdis[], double *maxtot, double avgdis[], double *avgtot, double rmsdis[], double *rmstot)

Compute measures of distortion.

Variables

```
    const char * dis_errmsg []
    Status return messages.
```

6.3.1 Detailed Description

Routines in this suite implement extensions to the FITS World Coordinate System (WCS) standard proposed by "Representations of distortions in FITS world coordinate systems", Calabretta, M.R. et al. (WCS Paper IV, draft dated 2004/04/22), available from http://www.atnf.csiro.au/people/Mark.Calabretta

In brief, a distortion function may occupy one of two positions in the WCS algorithm chain. Prior distortions precede the linear transformation matrix, whether it be PCi_ja or CDi_ja , and sequent distortions follow it. WCS Paper IV defines FITS keywords used to specify parameters for predefined distortion functions. The following are used for prior distortions:

```
CPDISja ...(string-valued, identifies the distortion function)
DPja ...(record-valued, parameters)
CPERRja ...(floating-valued, maximum value)
```

Their counterparts for sequent distortions are CQDISia, DQia, and CQERRia. An additional floating-valued keyword, DVERRa, records the maximum value of the combined distortions.

DPja and DQia are "record-valued". Syntactically, the keyvalues are standard FITS strings, but they are to be interpreted in a special way. The general form is

DPja = '<field-specifier>: <float>'

```
where the field-specifier consists of a sequence of fields separated by periods, and the ': ' between the field-specifier and the floating-point value is part of the record syntax. For example:
```

Certain field-specifiers are defined for all distortion functions, while others are defined only for particular distortions. Refer to WCS Paper IV for further details. wcspih() parses all distortion keywords and loads them into a disprm struct for analysis by disset() which knows (or possibly does not know) how to interpret them. Of the Paper IV distortion functions, only the general Polynomial distortion is currently implemented here.

TPV - the TPV "projection":

The distortion function component of the **TPV** celestial "projection" is also supported. The **TPV** projection, originally proposed in a draft of WCS Paper II, consists of a **TAN** projection with sequent polynomial distortion, the coefficients of which are encoded in **PV**i_ma keyrecords. Full details may be found at the registry of FITS conventions: http://fits.gsfc.nasa.gov/registry/tpvwcs/tpv.html

Internally, wcsset() changes **TPV** to a **TAN** projection, translates the **PV**i_ma keywords to **DQ**ia and loads them into a disprm struct. These **DQ**ia keyrecords have the form

DOia = 'TPV.m: <value>'

where i, a, m, and the value for each **DQ**ia match each **PV**i_ma. Consequently, WCSLIB would handle a FITS header containing these keywords, along with **CQDIS**ia = '**TPV**' and the required **DQ**ia.**NAXES** and **DQ**ia.**AXIS**.ihat keywords.

Note that, as defined, **TPV** assumes that **CD**i_ja is used to define the linear transformation. The section on historical idiosyncrasies (below) cautions about translating **CD**i_ja to **PC**i_ja plus **CDELT**ia in this case.

SIP - Simple Imaging Polynomial:

These routines also support the Simple Imaging Polynomial (SIP), whose design was influenced by early drafts of WCS Paper IV. It is described in detail in

```
http://fits.gsfc.nasa.gov/registry/sip.html
```

SIP, which is defined only as a prior distortion for 2-D celestial images, has the interesting feature that it records an approximation to the inverse polynomial distortion function. This is used by disx2p() to provide an initial estimate

for its more precise iterative inversion. The special-purpose keywords used by SIP are parsed and translated by wcspih() as follows:

```
A_p_q = <value> -> DP1 = 'SIP.FWD.p_q: <value>'
AP_p_q = <value> -> DP1 = 'SIP.REV.p_q: <value>'
B_p_q = <value> -> DP2 = 'SIP.FWD.p_q: <value>'
BP_p_q = <value> -> DP2 = 'SIP.REV.p_q: <value>'
BP_p_q = <value> -> DP2 = 'SIP.REV.p_q: <value>'
A_DMAX = <value> -> DPERR1 = <value>
B_DMAX = <value> -> DPERR2 = <value>
```

SIP's A_ORDER and B_ORDER keywords are not used. WCSLIB would recognise a FITS header containing the above keywords, along with CPDIS ja = 'SIP' and the required DP ja . NAXES keywords.

DSS - Digitized Sky Survey:

The Digitized Sky Survey resulted from the production of the Guide Star Catalogue for the Hubble Space Telescope. Plate solutions based on a polynomial distortion function were encoded in FITS using non-standard keywords. Sect. 5.2 of WCS Paper IV describes how **DSS** coordinates may be translated to a sequent Polynomial distortion using two auxiliary variables. That translation is based on optimising the non-distortion component of the plate solution.

Following Paper IV, wcspih() translates the non-distortion component of **DSS** coordinates to standard WCS keywords (**CRPIX**ja, **PC**i_ja, **CRVAL**ia, etc), and fills a wcsprm struct with their values. It encodes the **DSS** polynomial coefficients as

```
AMDXm = <value> -> DQ1 = 'AMD.m: <value>'
AMDYm = <value> -> DQ2 = 'AMD.m: <value>'
```

WCSLIB would recognise a FITS header containing the above keywords, along with CQDISia = 'DSS' and the required DQia. NAXES keywords.

WAT - the TNX and ZPX "projections":

The **TNX** and **ZPX** "projections" add a polynomial distortion function to the standard **TAN** and **ZPN** projections respectively. Unusually, the polynomial may be expressed as the sum of Chebyshev or Legendre polynomials, or as a simple sum of monomials, as described in

```
http://fits.gsfc.nasa.gov/registry/tnx/tnx-doc.html
http://fits.gsfc.nasa.gov/registry/zpxwcs/zpx.html
```

The polynomial coefficients are encoded in special-purpose **WAT**i_n keywords as a set of continued strings, thus providing the name for this distortion type. **WAT**i_n are parsed and translated by wcspih() into the following set:

```
DQi = 'WAT.POLY: <value>'
DQi = 'WAT.XMIN: <value>'
DQi = 'WAT.XMAX: <value>'
DQi = 'WAT.XMAX: <value>'
DQi = 'WAT.YMAX: <value>'
DQi = 'WAT.CHBY.m_n: <value>'
DQi = 'WAT.LEGR.m_n: <value>'
OQi = 'WAT.MONO.m_n: <value>'
```

along with CQDISia = 'WAT' and the required DPja. NAXES keywords. For ZPX, the ZPN projection parameters are also encoded in WATi_n, and wcspih() translates these to standard PVi_ma.

Note that, as defined, **TNX** and **ZPX** assume that **CD**i_ja is used to define the linear transformation. The section on historical idiosyncrasies (below) cautions about translating **CD**i_ja to **PC**i_ja plus **CDELT**ia in this case.

TPD - Template Polynomial Distortion:

The "Template Polynomial Distortion" (TPD) is a superset of the TPV, SIP, DSS, and WAT (TNX & ZPX) polynomial distortions that also supports 1-D usage and inversions. Like TPV, SIP, and DSS, the form of the polynomial is fixed (the "template") and only the coefficients for the required terms are set non-zero. TPD generalizes TPV in going to 9th degree, SIP by accommodating TPV's linear and radial terms, and DSS in both respects. While in theory the degree of the WAT polynomial distortion in unconstrained, in practice it is limited to values that can be handled by TPD.

Within WCSLIB, **TPV**, **SIP**, **DSS**, and **WAT** are all implemented as special cases of **TPD**. Indeed, **TPD** was developed precisely for that purpose. **WAT** distortions expressed as the sum of Chebyshev or Legendre polynomials are expanded for **TPD** as a simple sum of monomials. Moreover, the general Polynomial distortion is translated and implemented internally as **TPD** whenever possible.

However, WCSLIB also recognizes 'TPD' as a distortion function in its own right (i.e. a recognized value of CPDISja or CQDISia), for use as both prior and sequent distortions. Its DPja and DQia keyrecords have the form

```
DPja = 'TPD.FWD.m: <value>'
DPja = 'TPD.REV.m: <value>'
```

for the forward and reverse distortion functions. Moreover, like the general Polynomial distortion, **TPD** supports auxiliary variables, though only as a linear transformation of pixel coordinates (p1,p2):

```
x = a0 + a1*p1 + a2*p2

y = b0 + b1*p1 + b2*p2
```

where the coefficients of the auxiliary variables (x,y) are recorded as

```
DPja = 'AUX.1.COEFF.0: a0' ...default 0.0

DPja = 'AUX.1.COEFF.1: a1' ...default 1.0

DPja = 'AUX.1.COEFF.2: a2' ...default 0.0

DPja = 'AUX.2.COEFF.0: b0' ...default 0.0

DPja = 'AUX.2.COEFF.1: b1' ...default 0.0

DPja = 'AUX.2.COEFF.2: b2' ...default 1.0
```

Though nowhere near as powerful, in typical applications **TPD** is considerably faster than the general Polynomial distortion. As **TPD** has a finite and not too large number of possible terms (60), the coefficients for each can be stored (by disset()) in a fixed location in the disprm::dparm[] array. A large part of the speedup then arises from evaluating the polynomial using Horner's scheme.

Separate implementations for polynomials of each degree, and conditionals for 1-D polynomials and 2-D polynomials with and without the radial variable, ensure that unused terms mostly do not impose a significant computational overhead.

```
The TPD terms are as follows
```

```
0: 1
         4: xx
                     12: xxxx
                                   24: xxxxxx
                                                    40: xxxxxxxx
         5: xv
                    13: xxxv

                                    38: ууууууу
                                                    54: xxxxvvvvv
                                    39: rrrrrrr
                                                    55: xxxyyyyyy
                                                    56: ххуууууу
                                                    57: xyyyyyyyy
                                                    58: уууууууу
                                                    59: rrrrrrrr
```

where $r = \sqrt{(x^2 + y^2)}$. Note that even powers of r are excluded since they can be accommodated by powers of $(x^2 + y^2)$.

Note here that "x" refers to the axis to which the distortion function is attached, with "y" being the complementary axis. So, for example, with longitude on axis 1 and latitude on axis 2, for **TPD** attached to axis 1, "x" refers to axis 1 and "y" to axis 2. For **TPD** attached to axis 2, "x" refers to axis 2, and "y" to axis 1.

TPV uses all terms up to 39. The m in its PVi_ma keywords translates directly to the TPD coefficient number.

SIP uses all terms except for 0, 3, 11, 23, 39, and 59, with terms 1 and 2 only used for the inverse. Its \mathbf{A}_p_q , etc. keywords must be translated using a map.

DSS uses terms 0, 1, 2, 4, 5, 6, 7, 8, 9, 10, 17, 19, and 21. The presence of a non-zero constant term arises through the use of auxiliary variables with origin offset from the reference point of the **TAN** projection. However, in the translation given by WCS Paper IV, the distortion polynomial is zero, or very close to zero, at the reference pixel itself. The mapping between **DSS**'s **AMDX**m (or **AMDY**m) keyvalues and **TPD** coefficients, while still simple, is not quite as straightforward as for **TPV** and **SIP**.

WAT uses all but the radial terms, namely 3, 11, 23, 39, and 59. While the mapping between **WAT**'s monomial coefficients and **TPD** is fairly simple, for its expression in terms of a sum of Chebyshev or Legendre polynomials it is much less so.

Historical idiosyncrasies:

In addition to the above, some historical distortion functions have further idiosyncrasies that must be taken into account when translating them to **TPD**.

WCS Paper IV specifies that a distortion function returns a correction to be added to pixel coordinates (prior distortion) or intermediate pixel coordinates (sequent distortion). The correction is meant to be small so that ignoring the distortion function, i.e. setting the correction to zero, produces a commensurately small error.

However, rather than an additive correction, some historical distortion functions (**TPV**, **DSS**) define a polynomial that returns the corrected coordinates directly.

The difference between the two approaches is readily accounted for simply by adding or subtracting 1 from the coefficient of the first degree term of the polynomial. However, it opens the way for considerable confusion.

Additional to the formalism of WCS Paper IV, both the Polynomial and **TPD** distortion functions recognise a keyword DPja = 'DOCORR: 0'

which is meant to apply generally to indicate that the distortion function returns the corrected coordinates directly. Any other value for **DOCORR** (or its absence) indicates that the distortion function returns an additive correction.

WCS Paper IV also specifies that the independent variables of a distortion function are pixel coordinates (prior distortion) or intermediate pixel coordinates (sequent distortion).

On the contrary, the independent variables of the SIP polynomial are pixel coordinate offsets from the reference pixel. This is readily handled via the renormalisation parameters

DPja = 'OFFSET.jhat: <value>'

where the value corresponds to CRPIX ja.

Likewise, because **TPV**, **TNX**, and **ZPX** are defined in terms of **CD**i_ja, the independent variables of the polynomial are intermediate world coordinates rather than intermediate pixel coordinates. Because sequent distortions are always applied before **CDELT**ia, if **CD**i_ja is translated to **PC**i_ja plus **CDELT**ia, then either **CDELT**ia must be unity, or the distortion polynomial coefficients must be adjusted to account for the change of scale.

Summary of the dis routines:

These routines apply the distortion functions defined by the extension to the FITS WCS standard proposed in Paper IV. They are based on the disprm struct which contains all information needed for the computations. The struct contains some members that must be set by the user, and others that are maintained by these routines, somewhat like a C++ class but with no encapsulation.

dpfill(), dpkeyi(), and dpkeyd() are provided to manage the dpkey struct.

disndp(), disini(), disinit(), discpy(), and disfree() are provided to manage the disprm struct, dissize() computes its total size including allocated memory, disenq() returns information about the state of the struct, and disprt() prints its contents.

disperr() prints the error message(s) (if any) stored in a disprm struct.

wcshdo() normally writes SIP and TPV headers in their native form if at all possible. However, dishdo() may be used to set a flag that tells it to write the header in the form of the TPD translation used internally.

A setup routine, disset(), computes intermediate values in the disprm struct from parameters in it that were supplied by the user. The struct always needs to be set up by disset(), though disset() need not be called explicitly - refer to the explanation of disprm::flag.

disp2x() and disx2p() implement the WCS distortion functions, disp2x() using separate functions, such as dispoly() and tpd7(), to do the computation.

An auxiliary routine, diswarp(), computes various measures of the distortion over a specified range of coordinates.

PLEASE NOTE:

6.3.2 Macro Definition Documentation

DISP2X ARGS

#define DISP2X_ARGS

Value:

```

6.3.4 Function Documentation

disndp()

```
\quad \text{int disndp (} \\ \quad \text{int } n \text{ )}
```

Memory allocation for DP ja and DQia.

disndp() sets or gets the value of NDPMAX (default 256). This global variable controls the maximum number of dpkey structs, for holding DP ja or DQia keyvalues, that disini() should allocate space for. It is also used by disinit() as the default value of ndpmax.

PLEASE NOTE: This function is not thread-safe.

Parameters

```
in Value of NDPMAX; ignored if < 0. Use a value less than zero to get the current value.
```

Returns

Current value of NDPMAX.

dpfill()

Fill the contents of a dpkey struct.

dpfill() is a utility routine to aid in filling the contents of the dpkey struct. No checks are done on the validity of the inputs.

```
WCS Paper IV specifies the syntax of a record-valued keyword as keyword = '<field-specifier>: <float>'
```

However, some DPja and DQia record values, such as those of DPja.NAXES and DPja.AXIS.j, are intrinsically integer-valued. While FITS header parsers are not expected to know in advance which of DPja and DQia are integral and which are floating point, if the record's value parses as an integer (i.e. without decimal point or exponent), then preferably enter it into the dpkey struct as an integer. Either way, it doesn't matter as disset() accepts either data type for all record values.

Parameters

in, out	dp	Store for DP ja and DQia keyvalues.
in	keyword	
in	field	These arguments are concatenated with an intervening "." to construct the full record field name, i.e. including the keyword name, DPja or DQia (but excluding the colon delimiter which is NOT part of the name). Either may be given as a NULL pointer. Set both NULL to omit setting this component of the struct.
in	j	Axis number (1-relative), i.e. the j in DP ja or i in DQ ia. Can be given as 0, in which case the axis number will be obtained from the keyword component of the field name which must either have been given or preset. If j is non-zero, and keyword was given, then the value of j will be used to fill in the axis number.
in	type	Data type of the record's value • 0: Integer, • 1: Floating point.
in	i	For type == 0, the integer value of the record.
in	f	For type == 1, the floating point value of the record.

Returns

Status return value:

• 0: Success.

dpkeyi()

```
int dpkeyi ( {\tt const\ struct\ dpkey*\ } dp\ )
```

Get the data value in a dpkey struct as int.

dpkeyi() returns the data value in a dpkey struct as an integer value.

Parameters

in,out	dp	Parsed contents of a DP ja or DQia keyrecord.
--------	----	---

Returns

The record's value as int.

dpkeyd()

```
double dpkeyd ( {\tt const\ struct\ dpkey*\ dp\ )}
```

Get the data value in a dpkey struct as double.

dpkeyd() returns the data value in a dpkey struct as a floating point value.

Parameters

in,out	dp	Parsed contents of a DP ja or DQia keyrecord.	1
--------	----	---	---

Returns

The record's value as double.

disini()

```
int disini (
                int alloc,
                int naxis,
                struct disprm * dis )
```

Default constructor for the disprm struct.

disini() is a thin wrapper on disinit(). It invokes it with ndpmax set to -1 which causes it to use the value of the global variable NDPMAX. It is thereby potentially thread-unsafe if NDPMAX is altered dynamically via disndp(). Use disinit() for a thread-safe alternative in this case.

disinit()

```
int disinit (
                int alloc,
                int naxis,
                struct disprm * dis,
                 int ndpmax )
```

Default constructor for the disprm struct.

disinit() allocates memory for arrays in a disprm struct and sets all members of the struct to default values.

PLEASE NOTE: every disprm struct must be initialized by **disinit**(), possibly repeatedly. On the first invokation, and only the first invokation, disprm::flag must be set to -1 to initialize memory management, regardless of whether **disinit**() will actually be used to allocate memory.

Parameters

in	alloc	If true, allocate memory unconditionally for arrays in the disprm struct. If false, it is assumed that pointers to these arrays have been set by the user except if they are null pointers in which case memory will be allocated for them regardless. (In other words, setting alloc true saves having to initalize these pointers to zero.)
in	naxis	The number of world coordinate axes, used to determine array sizes.
in,out	dis	Distortion function parameters. Note that, in order to initialize memory management disprm::flag must be set to -1 when dis is initialized for the first time (memory leaks may result if it had already been initialized).
in	ndpmax	The number of DP ja or DQ ia keywords to allocate space for. If set to -1, the value of the global variable NDPMAX will be used. This is potentially thread-unsafe if disndp() is being used dynamically to alter its value.

Returns

Status return value:

- · 0: Success.
- 1: Null disprm pointer passed.
- 2: Memory allocation failed.

For returns > 1, a detailed error message is set in disprm::err if enabled, see wcserr_enable().

discpy()

Copy routine for the disprm struct.

discpy() does a deep copy of one disprm struct to another, using disinit() to allocate memory unconditionally for its arrays if required. Only the "information to be provided" part of the struct is copied; a call to disset() is required to initialize the remainder.

Parameters

in	alloc	If true, allocate memory unconditionally for arrays in the destination. Otherwise, it is assumed that pointers to these arrays have been set by the user except if they are null pointers in which case memory will be allocated for them regardless.	
in	dissrc	Struct to copy from.	
in,out	disdst	Struct to copy to. disprm::flag should be set to -1 if disdst was not previously initialized (memory leaks may result if it was previously initialized).	

Returns

Status return value:

- 0: Success.
- 1: Null disprm pointer passed.
- 2: Memory allocation failed.

For returns > 1, a detailed error message is set in disprm::err if enabled, see wcserr_enable().

disfree()

```
int disfree ( {\tt struct\ disprm\ *\ dis\ )}
```

Destructor for the disprm struct.

disfree() frees memory allocated for the disprm arrays by disinit(). disinit() keeps a record of the memory it allocates and disfree() will only attempt to free this.

PLEASE NOTE: disfree() must not be invoked on a disprm struct that was not initialized by disinit().

Parameters

n dis Distortion function parameters.	in <i>dis</i>
---------------------------------------	---------------

Returns

Status return value:

- 0: Success.
- 1: Null disprm pointer passed.

dissize()

```
int dissize ( {\rm const\ struct\ disprm\ *\ } dis, {\rm int\ } sizes[2]\ )
```

Compute the size of a disprm struct.

dissize() computes the full size of a disprm struct, including allocated memory.

Parameters

in	dis	Distortion function parameters.
		If NULL, the base size of the struct and the allocated size are both set to zero.
out	sizes	The first element is the base size of the struct as returned by sizeof(struct disprm). The second element is the total allocated size, in bytes, assuming that the allocation was done by disini(). This figure includes memory allocated for members of constituent structs, such as disprm::dp. It is not an error for the struct not to have been set up via tabset(), which normally results in additional memory allocation.

Returns

Status return value:

• 0: Success.

disenq()

```
int disenq ( {\rm const\ struct\ disprm\ *\ dis}, int {\it enquiry} )
```

enquire about the state of a disprm struct.

disenq() may be used to obtain information about the state of a disprm struct. The function returns a true/false answer for the enquiry asked.

Parameters

in	dis	Distortion function parameters.
in	enquiry	Enquiry according to the following parameters:
		DISENQ_MEM: memory in the struct is being managed by WCSLIB (see disinit()).
		 DISENQ_SET: the struct has been set up by disset().
		 DISENQ_BYP: the struct is in bypass mode (see disset()).
		These may be combined by logical OR, e.g. DISENQ_MEM DISENQ_SET. The enquiry result will be the logical AND of the individual results.

Returns

Enquiry result:

- 0: No.
- 1: Yes.

disprt()

```
int disprt ( {\tt const\ struct\ disprm\ *\ dis\ )}
```

Print routine for the disprm struct.

disprt() prints the contents of a disprm struct using wcsprintf(). Mainly intended for diagnostic purposes.

Parameters

in	dis	Distortion function parameters.
----	-----	---------------------------------

Returns

Status return value:

- 0: Success.
- 1: Null disprm pointer passed.

disperr()

Print error messages from a disprm struct.

disperr() prints the error message(s) (if any) stored in a disprm struct. If there are no errors then nothing is printed. It uses wcserr_prt(), q.v.

Parameters

in	dis	Distortion function parameters.
in	prefix	If non-NULL, each output line will be prefixed with this string.

Returns

Status return value:

- 0: Success.
- 1: Null disprm pointer passed.

dishdo()

```
int dishdo ( {\tt struct\ disprm\ *\ dis\ )}
```

write FITS headers using TPD.

dishdo() sets a flag that tells wcshdo() to write FITS headers in the form of the **TPD** translation used internally. Normally **SIP** and **TPV** would be written in their native form if at all possible.

Parameters

in,ou	t dis	Distortion function parameters.
-------	-------	---------------------------------

Returns

Status return value:

- 0: Success.
- 1: Null disprm pointer passed.
- 3: No TPD translation.

disset()

```
int disset ( {\tt struct\ disprm\ *\ dis\ )}
```

Setup routine for the disprm struct.

 $\textbf{disset}(), sets up the \\ \textbf{disprm} \ struct \ according \ to \ information \ supplied \ within \ it - refer \ to \ the \ explanation \ of \\ \textbf{disprm} \ :: flag.$

Note that this routine need not be called directly; it will be invoked by disp2x() and disx2p() if the disprm::flag is anything other than a predefined magic value.

disset() normally operates regardless of the value of disprm::flag; i.e. even if a struct was previously set up it will be reset unconditionally. However, a disprm struct may be put into "bypass" mode by invoking **disset**() initially with disprm::flag == 1 (rather than 0). **disset**() will return immediately if invoked on a struct in that state. To take a struct out of bypass mode, simply reset disprm::flag to zero. See also disenq().

Parameters

in,out	dis	Distortion function parameters.
--------	-----	---------------------------------

Returns

Status return value:

- · 0: Success.
- 1: Null disprm pointer passed.
- 2: Memory allocation failed.
- · 3: Invalid parameter.

For returns > 1, a detailed error message is set in disprm::err if enabled, see wcserr_enable().

disp2x()

Apply distortion function.

disp2x() applies the distortion functions. By definition, the distortion is in the pixel-to-world direction.

Depending on the point in the algorithm chain at which it is invoked, **disp2x**() may transform pixel coordinates to corrected pixel coordinates, or intermediate pixel coordinates to corrected intermediate pixel coordinates, or image coordinates to corrected image coordinates.

disx2p()

Apply de-distortion function.

disx2p() applies the inverse of the distortion functions. By definition, the de-distortion is in the world-to-pixel direction.

Depending on the point in the algorithm chain at which it is invoked, **disx2p**() may transform corrected pixel coordinates to pixel coordinates, or corrected intermediate pixel coordinates to intermediate pixel coordinates, or corrected image coordinates to image coordinates.

disx2p() iteratively solves for the inverse using disp2x(). It assumes that the distortion is small and the functions are well-behaved, being continuous and with continuous derivatives. Also that, to first order in the neighbourhood of the solution, $discrd[j] \sim = a + b*rawcrd[j]$, i.e. independent of rawcrd[i], where i != j. This is effectively equivalent to assuming that the distortion functions are separable to first order. Furthermore, a is assumed to be small, and b close to unity.

If disprm::disx2p() is defined, then disx2p() uses it to provide an initial estimate for its more precise iterative inversion.

Parameters

in,out	dis	Distortion function parameters.
in	discrd	Array of coordinates.
out	rawcrd	Array of coordinates to which the inverse distortion functions have been applied.

Returns

Status return value:

- · 0: Success.
- 1: Null disprm pointer passed.
- 2: Memory allocation failed.
- · 3: Invalid parameter.
- · 5: De-distort error.

For returns > 1, a detailed error message is set in disprm::err if enabled, see wcserr_enable().

diswarp()

Compute measures of distortion.

diswarp() computes various measures of the distortion over a specified range of coordinates.

For prior distortions, the measures may be interpreted simply as an offset in pixel coordinates. For sequent distortions, the interpretation depends on the nature of the linear transformation matrix (\mathbf{PC}_{-ja} or \mathbf{CD}_{-ja}). If the latter introduces a scaling, then the measures will also be scaled. Note also that the image domain, which is rectangular in pixel coordinates, may be rotated, skewed, and/or stretched in intermediate pixel coordinates, and in general cannot be defined using pixblc[] and pixtrc[].

PLEASE NOTE: the measures of total distortion may be essentially meaningless if there are multiple sequent distortions with different scaling.

See also linwarp().

Parameters

in,out	dis	Distortion function parameters.
in	pixblc	Start of the range of pixel coordinates (for prior distortions), or intermediate pixel coordinates (for sequent distortions). May be specified as a NULL pointer which is interpreted as (1,1,).

Parameters

in	pixtrc	End of the range of pixel coordinates (prior) or intermediate pixel coordinates (sequent).
in	pixsamp	If positive or zero, the increment on the particular axis, starting at pixblc[]. Zero is interpreted as a unit increment. pixsamp may also be specified as a NULL pointer which is interpreted as all zeroes, i.e. unit increments on all axes. If negative, the grid size on the particular axis (the absolute value being rounded to the nearest integer). For example, if pixsamp is (-128.0,-128.0,) then each axis will be sampled at 128 points between pixblc[] and pixtrc[] inclusive. Use caution when using this option on non-square images.
out	nsamp	The number of pixel coordinates sampled. Can be specified as a NULL pointer if not required.
out	maxdis	For each individual distortion function, the maximum absolute value of the distortion. Can be specified as a NULL pointer if not required.
out	maxtot	For the combination of all distortion functions, the maximum absolute value of the distortion. Can be specified as a NULL pointer if not required.
out	avgdis	For each individual distortion function, the mean value of the distortion. Can be specified as a NULL pointer if not required.
out	avgtot	For the combination of all distortion functions, the mean value of the distortion. Can be specified as a NULL pointer if not required.
out	rmsdis	For each individual distortion function, the root mean square deviation of the distortion. Can be specified as a NULL pointer if not required.
out	rmstot	For the combination of all distortion functions, the root mean square deviation of the distortion. Can be specified as a NULL pointer if not required.

Returns

Status return value:

- 0: Success.
- 1: Null disprm pointer passed.
- 2: Memory allocation failed.
- 3: Invalid parameter.
- 4: Distort error.

6.3.5 Variable Documentation

dis_errmsg

```
const char * dis_errmsg[] [extern]
```

Status return messages.

Error messages to match the status value returned from each function.

6.4 dis.h

Go to the documentation of this file.

00023 *====
00024 *
00025 * WCSLIB 8.3 - C routines that implement the FITS World Coordinate System
00026 \star (WCS) standard. Refer to the README file provided with WCSLIB for an
00027 * overview of the library.
00028 *
00029 *
00030 * Summary of the dis routines
00031 *
00032 \star Routines in this suite implement extensions to the FITS World Coordinate
00033 * System (WCS) standard proposed by
00034 *
00035 =
          "Representations of distortions in FITS world coordinate systems",
00036 =
          Calabretta, M.R. et al. (WCS Paper IV, draft dated 2004/04/22),
00037 =
          available from http://www.atnf.csiro.au/people/Mark.Calabretta
00038 *
00039 \star In brief, a distortion function may occupy one of two positions in the WCS
00040 \star algorithm chain. Prior distortions precede the linear transformation
00041 \star matrix, whether it be PCi_ja or CDi_ja, and sequent distortions follow it.
00042 \star WCS Paper IV defines FITS keywords used to specify parameters for predefined
00043 \star distortion functions. The following are used for prior distortions:
00044 *
00045 =
          CPDISja
                     ...(string-valued, identifies the distortion function)
00046 =
                     ... (record-valued, parameters)
00047 =
          CPERRja
                     ...(floating-valued, maximum value)
00048 *
00049 \star Their counterparts for sequent distortions are CQDISia, DQia, and CQERRia.
00050 \star An additional floating-valued keyword, DVERRa, records the maximum value of
00051 * the combined distortions.
00052 *
00053 \star DPja and DQia are "record-valued". Syntactically, the keyvalues are
00054 \star standard FITS strings, but they are to be interpreted in a special way.
00055 * The general form is
00056 *
00057 =
          DPja = '<field-specifier>: <float>'
00058 *
00059 \star where the field-specifier consists of a sequence of fields separated by
00060 \star periods, and the ': ' between the field-specifier and the floating-point
00061 * value is part of the record syntax. For example:
00062 *
00063 =
          DP1 = 'AXIS.1: 1'
00064 *
00065 \star Certain field-specifiers are defined for all distortion functions, while
00066 \star others are defined only for particular distortions. Refer to WCS Paper IV
00067 \star for further details. wcspih() parses all distortion keywords and loads them 00068 \star into a disprm struct for analysis by disset() which knows (or possibly does 00069 \star not know) how to interpret them. Of the Paper IV distortion functions, only
00070 * the general Polynomial distortion is currently implemented here.
00071 *
00072 * TPV - the TPV "projection":
00073 * ---
00074 * The distortion function component of the TPV celestial "projection" is also
00075 \star supported. The TPV projection, originally proposed in a draft of WCS Paper
00076 \, \star \, \text{II, consists} of a TAN projection with sequent polynomial distortion, the
00077 \star coefficients of which are encoded in PVi_ma keyrecords. Full details may be
00078 \star found at the registry of FITS conventions:
00079 *
00080 =
          http://fits.gsfc.nasa.gov/registry/tpvwcs/tpv.html
00081 *
00082 * Internally, wcsset() changes TPV to a TAN projection, translates the PVi_ma
00083 \star keywords to DQia and loads them into a disprm struct. These DQia keyrecords
```

```
00084 \star have the form
00085 *
00086 =
          DOia = 'TPV.m: <value>'
00087 *
00088 \star where i, a, m, and the value for each DQia match each PVi_ma. Consequently, 00089 \star WCSLIB would handle a FITS header containing these keywords, along with
00090 \star CQDISia = 'TPV' and the required DQia.NAXES and DQia.AXIS.ihat keywords.
00091 *
00092 \star Note that, as defined, TPV assumes that CDi_ja is used to define the linear
00093 \star transformation. The section on historical idiosyncrasies (below) cautions
00094 * about translating CDi_ja to PCi_ja plus CDELTia in this case.
00095 *
00096 * SIP - Simple Imaging Polynomial:
00097 *
00098 \star These routines also support the Simple Imaging Polynomial (SIP), whose
00099 \star design was influenced by early drafts of WCS Paper IV. It is described in
00100 * detail in
00101 *
          http://fits.gsfc.nasa.gov/registry/sip.html
00103 *
00104 \star SIP, which is defined only as a prior distortion for 2-D celestial images,
00105 \star has the interesting feature that it records an approximation to the inverse
00106 \star polynomial distortion function. This is used by disx2p() to provide an
00107 \star initial estimate for its more precise iterative inversion. The
00108 * special-purpose keywords used by SIP are parsed and translated by wcspih()
00109 * as follows:
00110 *
           A_p_q = \langle value \rangle
00111 =
                                    DP1 = 'SIP.FWD.p_q: <value>'
                              -> DP1 = 'SIP.FWD.p_q: \varue>'
-> DP1 = 'SIP.REV.p_q: \varue>'
00112 =
          AP_p_q = \langle value \rangle
           B_p_q = \langle value \rangle
                                    DP2 = 'SIP.FWD.p_q: <value>'
00113 =
                              ->
                                    DP2 = 'SIP.REV.p_q: <value>'
00114 =
                              ->
          BP_p_q = \langle value \rangle
00115 =
          A_DMAX = \langle value \rangle
                               ->
                                    DPERR1 = <value>
          B_DMAX = <value>
                                   DPERR2 = <value>
00116 =
00117 *
00118 \star SIP's A_ORDER and B_ORDER keywords are not used. WCSLIB would recognise a
00119 \star FITS header containing the above keywords, along with CPDISja = 'SIP' and
00120 * the required DPja.NAXES keywords.
00122 * DSS - Digitized Sky Survey:
00123 *
00124 \star The Digitized Sky Survey resulted from the production of the Guide Star
00125 \star Catalogue for the Hubble Space Telescope. Plate solutions based on a
00126 * polynomial distortion function were encoded in FITS using non-standard
00127 * keywords. Sect. 5.2 of WCS Paper IV describes how DSS coordinates may be
00128 \star translated to a sequent Polynomial distortion using two auxiliary variables.
00129 \star That translation is based on optimising the non-distortion component of the
00130 * plate solution.
00131 *
00132 * Following Paper IV, wcspih() translates the non-distortion component of DSS
00133 * coordinates to standard WCS keywords (CRPIXja, PCi_ja, CRVALia, etc), and
00134 * fills a wcsprm struct with their values. It encodes the DSS polynomial
00135 * coefficients as
00136 *
           AMDXm = <value> -> DQ1 = 'AMD.m: <value>'
AMDYm = <value> -> DQ2 = 'AMD.m: <value>'
00137 =
00138 =
00139 *
00140 * WCSLIB would recognise a FITS header containing the above keywords, along
00141 * with CQDISia = 'DSS' and the required DQia.NAXES keywords.
00142 *
00143 * WAT - the TNX and ZPX "projections":
00144 *
00145 \star The TNX and ZPX "projections" add a polynomial distortion function to the
00146 \star standard TAN and ZPN projections respectively. Unusually, the polynomial
00147 \star may be expressed as the sum of Chebyshev or Legendre polynomials, or as a
00148 \star simple sum of monomials, as described in
00149 *
00150 =
          http://fits.gsfc.nasa.gov/registry/tnx/tnx-doc.html
00151 =
          http://fits.gsfc.nasa.gov/registry/zpxwcs/zpx.html
00152 *
00153 * The polynomial coefficients are encoded in special-purpose WATi_n keywords
00154 \star as a set of continued strings, thus providing the name for this distortion
00155 \star type. WATi_n are parsed and translated by wcspih() into the following set:
00156 *
           DOi = 'WAT.POLY: <value>
00157 =
           DQi = 'WAT.XMIN: <value>'
00158 =
           DQi = 'WAT.XMAX: <value>'
00159 =
           DQi = 'WAT.YMIN: <value>'
00160 =
00161 =
           DQi = 'WAT.YMAX: <value>'
           DQi = 'WAT.CHBY.m_n: <value>'
00162 =
           DQi = 'WAT.LEGR.m_n: <value>'
00163 =
                                            or
           DQi = 'WAT.MONO.m_n: <value>'
00164 =
00165 *
00166 \star along with CQDISia = 'WAT' and the required DPja.NAXES keywords. For ZPX,
00167 \star the ZPN projection parameters are also encoded in WATi_n, and wcspih()
00168 \star translates these to standard PVi_ma.
00169
00170 * Note that, as defined, TNX and ZPX assume that CDi ja is used to define the
```

```
00171 \star linear transformation. The section on historical idiosyncrasies (below)
00172 \star cautions about translating CDi_ja to PCi_ja plus CDELTia in this case.
00173 *
00174 * TPD - Template Polynomial Distortion:
00175 * ---
00176 \star The "Template Polynomial Distortion" (TPD) is a superset of the TPV, SIP,
00177 \star DSS, and WAT (TNX \& ZPX) polynomial distortions that also supports 1-D usage
00178 \star and inversions. Like TPV, SIP, and DSS, the form of the polynomial is fixed 00179 \star (the "template") and only the coefficients for the required terms are set
00180 \star non-zero. TPD generalizes TPV in going to 9th degree, SIP by accomodating
00181 * TPV's linear and radial terms, and DSS in both respects. While in theory
00182 \star the degree of the WAT polynomial distortion in unconstrained, in practice it
00183 * is limited to values that can be handled by TPD.
00184 *
00185 \star Within WCSLIB, TPV, SIP, DSS, and WAT are all implemented as special cases
00186 \star of TPD. Indeed, TPD was developed precisely for that purpose. WAT 00187 \star distortions expressed as the sum of Chebyshev or Legendre polynomials are
00188 * expanded for TPD as a simple sum of monomials. Moreover, the general
00189 \star Polynomial distortion is translated and implemented internally as TPD
00190 \star whenever possible.
00191 *
00192 \star However, WCSLIB also recognizes 'TPD' as a distortion function in its own
00193 \star right (i.e. a recognized value of CPDISja or CQDISia), for use as both prior
00194 \star and sequent distortions. Its DPja and DQia keyrecords have the form
00195 *
00196 =
          DPja = 'TPD.FWD.m: <value>'
00197 =
          DPja = 'TPD.REV.m: <value>'
00198 *
00199 \star for the forward and reverse distortion functions. Moreover, like the
00200 \star general Polynomial distortion, TPD supports auxiliary variables, though only 00201 \star as a linear transformation of pixel coordinates (p1,p2):
00202 *
00203 =
          x = a0 + a1*p1 + a2*p2
00204 =
          y = b0 + b1*p1 + b2*p2
00205 *
00206 \star where the coefficients of the auxiliary variables (x,y) are recorded as
00207 *
                                               ...default 0.0
          DPja = 'AUX.1.COEFF.0: a0'
00209 =
           DPja = 'AUX.1.COEFF.1: a1'
                                               ...default 1.0
00210 =
           DPja = 'AUX.1.COEFF.2: a2'
                                               ...default 0.0
                                               ...default 0.0
00211 =
          DPja = 'AUX.2.COEFF.0: b0'
          DPja = 'AUX.2.COEFF.1: b1'
00212 =
                                               ...default 0.0
          DPja = 'AUX.2.COEFF.2: b2'
00213 =
                                               ...default 1.0
00215 \star Though nowhere near as powerful, in typical applications TPD is considerably
00216 \star faster than the general Polynomial distortion. As TPD has a finite and not
00217 \star too large number of possible terms (60), the coefficients for each can be
00218 \star stored (by disset()) in a fixed location in the disprm::dparm[] array. A
00219 \star large part of the speedup then arises from evaluating the polynomial using 00220 \star Horner's scheme.
00221 +
00222 \star Separate implementations for polynomials of each degree, and conditionals
00223 \star for 1-D polynomials and 2-D polynomials with and without the radial
00224 \star variable, ensure that unused terms mostly do not impose a significant
00225 * computational overhead.
00226 *
00227 * The TPD terms are as follows
00228 *
00229 =
          0: 1
                     4: xx
                                  12: xxxx
                                                 24: xxxxxx
                                                                   40: xxxxxxxx
                                                                   41: xxxxxxxy
00230 =
                     5: xy
                                 13: xxxy
                                                 25: xxxxxy
00231 =
          1: x
                    6: yy
                                 14: xxyy
                                                 26: xxxxvv
                                                                   42: xxxxxxvv
00232 =
          2: y
                                                 27: xxxyyy
                                  15: xyyy
                                                                   43: xxxxxvvv
                     7: xxx
00233 =
           3: r
                                 16: yyyy
                                                 28: xxyyyy
                                                                   44: xxxxyyyy
                                                 29: xyyyyy
                                                                    45: xxxyyyyy
00234 =
                     8: xxy
                     9: xyy
00235 =
                                  17: xxxxx
                                                                   46: xxyyyyyy
                                                 30: уууууу
                                 18: xxxxy
00236 =
                    10: yyy
                                                                   47: xyyyyyyy
                                                 31: xxxxxxx
00237 =
                    11: rrr
                                  19: xxxyy
                                                                   48: ууууууу
00238 =
                                  20: xxyyy
                                                 32: xxxxxxv
00239 =
                                                 33: xxxxxyy
                                                                   49: xxxxxxxx
                                 21: xyyyy
00240 =
                                  22: ууууу
                                                 34: xxxxyyy
                                                                    50: xxxxxxxxy
00241 =
                                                 35: xxxyyyy
                                                                    51: xxxxxxxyy
00242 =
                                                 36: ххууууу
                                                                    52: xxxxxxyyy
00243 =
                                                 37: хуууууу
                                                                    53: xxxxxyyyy
00244 =
                                                 38: ууууууу
                                                                    54: xxxxyyyyy
00245 =
                                                 39: rrrrrrr
                                                                    55: xxxvvvvvv
00246 =
                                                                    56: ххуууууу
00247 =
                                                                    57: xyyyyyyyy
00248 =
                                                                   58: уууууууу
00249 =
                                                                    59 · rrrrrrrr
00250 *
00251 * \text{where } r = \text{sqrt}(xx + yy). Note that even powers of r are excluded since they
00252 * can be accomodated by powers of (xx + yy).
00254 \star Note here that "x" refers to the axis to which the distortion function is
00255 * attached, with "y" being the complementary axis. So, for example, with
00256 * longitude on axis 1 and latitude on axis 2, for TPD attached to axis 1, "x" 00257 * refers to axis 1 and "y" to axis 2. For TPD attached to axis 2, "x" refers
```

```
00258 \star to axis 2, and "y" to axis 1.
00260 \star TPV uses all terms up to 39. The m in its PVi_ma keywords translates
00261 * directly to the TPD coefficient number.
00262 *
00263 \star SIP uses all terms except for 0, 3, 11, 23, 39, and 59, with terms 1 and 2
00264 \star only used for the inverse. Its A_p_q, etc. keywords must be translated
00265 * using a map.
00266
00267 \star DSS uses terms 0, 1, 2, 4, 5, 6, 7, 8, 9, 10, 17, 19, and 21. The presence
00268 * of a non-zero constant term arises through the use of auxiliary variables
00269 \star with origin offset from the reference point of the TAN projection. However,
00270 * in the translation given by WCS Paper IV, the distortion polynomial is zero,
00271 \, \star \, \text{or very close to zero, at the reference pixel itself.} The mapping between
00272 * DSS's AMDXm (or AMDYm) keyvalues and TPD coefficients, while still simple,
00273 \star is not quite as straightforward as for TPV and SIP.
00274 *
00275 * WAT uses all but the radial terms, namely 3, 11, 23, 39, and 59. While the
00276 * mapping between WAT's monomial coefficients and TPD is fairly simple, for
00277 * its expression in terms of a sum of Chebyshev or Legendre polynomials it is
00278 * much less so.
00279 *
00280 * Historical idiosyncrasies:
00281 * --
00282 * In addition to the above, some historical distortion functions have further
00283 \star idiosyncrasies that must be taken into account when translating them to TPD.
00284
00285 \star WCS Paper IV specifies that a distortion function returns a correction to be
00286 \star added to pixel coordinates (prior distortion) or intermediate pixel
00287 \star coordinates (sequent distortion). The correction is meant to be small so
00288 \star that ignoring the distortion function, i.e. setting the correction to zero,
00289 * produces a commensurately small error.
00290 *
00291 \star However, rather than an additive correction, some historical distortion
00292 \star functions (TPV, DSS) define a polynomial that returns the corrected 00293 \star coordinates directly.
00294
00295 \star The difference between the two approaches is readily accounted for simply by
00296 \star adding or subtracting 1 from the coefficient of the first degree term of the
00297 \star polynomial. However, it opens the way for considerable confusion.
00298 *
00299 * Additional to the formalism of WCS Paper IV, both the Polynomial and TPD
00300 \star distortion functions recognise a keyword
00301 *
00302 =
         DPja = 'DOCORR: 0'
00303 *
00304 \star which is meant to apply generally to indicate that the distortion function
00305 \star returns the corrected coordinates directly. Any other value for DOCORR (or 00306 \star its absence) indicates that the distortion function returns an additive
00307 * correction.
00308 +
00309 \star WCS Paper IV also specifies that the independent variables of a distortion
00310 \star function are pixel coordinates (prior distortion) or intermediate pixel
00311 \star coordinates (sequent distortion).
00312 *
00313 \star On the contrary, the independent variables of the SIP polynomial are pixel
00314 * coordinate offsets from the reference pixel. This is readily handled via
00315 * the renormalisation parameters
00316 *
00317 =
          DPja = 'OFFSET.jhat: <value>'
00318 *
00319 * where the value corresponds to CRPIXja.
00320 *
00321 \star Likewise, because TPV, TNX, and ZPX are defined in terms of CDi_ja, the
00322 \star independent variables of the polynomial are intermediate world coordinates
00323 \star rather than intermediate pixel coordinates. Because sequent distortions
00324 \star are always applied before CDELTia, if CDi_ja is translated to PCi_ja plus
00325 * CDELTia, then either CDELTia must be unity, or the distortion polynomial
00326 * coefficients must be adjusted to account for the change of scale.
00327 *
00328 * Summary of the dis routines:
00329 *
00330 \star These routines apply the distortion functions defined by the extension to
00331 \star the FITS WCS standard proposed in Paper IV. They are based on the disprm
00332 * struct which contains all information needed for the computations.
00333 \star struct contains some members that must be set by the user, and others that
00334 \star are maintained by these routines, somewhat like a C++ class but with no
00335 \star encapsulation.
00336 *
00337 * dpfill(), dpkeyi(), and dpkeyd() are provided to manage the dpkey struct.
00338 *
00339 \star disndp(), disini(), disinit(), discpy(), and disfree() are provided to
00340 \star manage the disprm struct, dissize() computes its total size including
00341 \star allocated memory, diseng() returns information about the state of the
00342 \star struct, and disprt() prints its contents.
00343
00344 * disperr() prints the error message(s) (if any) stored in a disprm struct.
```

```
00346 \star wcshdo() normally writes SIP and TPV headers in their native form if at all
00347 \star possible. However, dishdo() may be used to set a flag that tells it to
00348 * write the header in the form of the TPD translation used internally.
00349 *
00350 \star A setup routine, disset(), computes intermediate values in the disprm struct 00351 \star from parameters in it that were supplied by the user. The struct always
00352 \star needs to be set up by disset(), though disset() need not be called
00353 \star explicitly - refer to the explanation of disprm::flag.
00354 *
00355 * disp2x() and disx2p() implement the WCS distortion functions, disp2x() using
00356 \star separate functions, such as dispoly() and tpd7(), to do the computation.
00357 +
00358 \star An auxiliary routine, diswarp(), computes various measures of the distortion
00359 * over a specified range of coordinates.
00360
00361 \star PLEASE NOTE: Distortions are not yet handled by wcsbth(), or wcscompare().
00362 *
00363 *
00364 * disndp() - Memory allocation for DPja and DQia
00365 *
00366 \star disndp() sets or gets the value of NDPMAX (default 256). This global
00367 \star variable controls the maximum number of dpkey structs, for holding DPja or
00368 \star DQia keyvalues, that disini() should allocate space for. It is also used by
00369 \star disinit() as the default value of ndpmax.
00370 *
00371 * PLEASE NOTE: This function is not thread-safe.
00372 *
00373 * Given:
00374 *
         n
                     int
                                 Value of NDPMAX; ignored if < 0. Use a value less
00375 *
                                 than zero to get the current value.
00376 *
00377 * Function return value:
00378 *
                                 Current value of NDPMAX.
                      int
00379 *
00380 *
00381 * dpfill() - Fill the contents of a dpkey struct
00383 \star dpfill() is a utility routine to aid in filling the contents of the dpkey
00384 * struct. No checks are done on the validity of the inputs.
00385 *
00386 * WCS Paper IV specifies the syntax of a record-valued keyword as
00387 *
00388 =
          keyword = '<field-specifier>: <float>'
00389 *
00390 \star However, some DPja and DQia record values, such as those of DPja.NAXES and
00391 \star DPja.AXIS.j, are intrinsically integer-valued. While FITS header parsers
00392 \star are not expected to know in advance which of DPja and DQia are integral and
00393 \star which are floating point, if the record's value parses as an integer (i.e. 00394 \star without decimal point or exponent), then preferably enter it into the dpkey 00395 \star struct as an integer. Either way, it doesn't matter as disset() accepts
00396 * either data type for all record values.
00397 *
00398 \star Given and returned:
00399 *
          dp
                      struct dpkey*
00400 *
                                 Store for DPja and DOia keyvalues.
00401 *
00402 * Given:
00403 *
          keyword
                      const char *
00404 *
           field
                      const char *
                                 These arguments are concatenated with an intervening
00405 *
00406 *
                                  "." to construct the full record field name, i.e.
00407 *
                                 including the keyword name, DPja or DQia (but
00408 *
                                 excluding the colon delimiter which is NOT part of the
                                          Either may be given as a NULL pointer. Set
00409 *
                                 both NULL to omit setting this component of the
00410 *
00411 *
                                 struct.
00412 *
00413 *
                      int
                                 Axis number (1-relative), i.e. the i in DPia or
                                 i in DQia. Can be given as 0, in which case the axis
00414 *
00415 *
                                 number will be obtained from the keyword component of
00416 *
                                 the field name which must either have been given or
                                 preset.
00417 *
00418 *
                                 If j is non-zero, and keyword was given, then the value of j will be used to fill in the axis number.
00419 *
00420 *
00421 *
00422 *
                      int
                                 Data type of the record's value
00423 *
                                    0: Integer,
00424 *
                                   1: Floating point.
00425 *
00426 *
                      int
           i
                                 For type == 0, the integer value of the record.
00427 *
00428 *
                      double
                                 For type == 1, the floating point value of the record.
00429 *
00430 * Function return value:
00431 *
                                 Status return value:
                      int
```

```
00432 *
                                0: Success.
00433 *
00434
00435 \star dpkeyi() - Get the data value in a dpkey struct as int
00436 *
00437 \star dpkeyi() returns the data value in a dpkey struct as an integer value.
00439 * Given and returned:
00440 * dp
                  const struct dpkey *
00441 *
                              Parsed contents of a DPja or DQia keyrecord.
00442 *
00443 * Function return value:
00444 *
                              The record's value as int.
                   int
00445 *
00446 *
00447 \star dpkeyd() - Get the data value in a dpkey struct as double
00448 *
00449 * dpkeyd() returns the data value in a dpkey struct as a floating point
00450 * value.
00451
00452 * Given and returned:
00453 *
         dp
                   const struct dpkey *
00454 *
                              Parsed contents of a DPja or DQia keyrecord.
00455 *
00456 * Function return value:
                   double
                              The record's value as double.
00458 *
00459 *
00460 * disini() - Default constructor for the disprm struct
00461 * ---
00462 * disini() is a thin wrapper on disinit(). It invokes it with ndpmax set
00463 \star to -1 which causes it to use the value of the global variable NDPMAX.
00464 * is thereby potentially thread-unsafe if NDPMAX is altered dynamically via
00465 * disndp().
                   Use disinit() for a thread-safe alternative in this case.
00466 *
00467
00468 * disinit() - Default constructor for the disprm struct
00470 \star disinit() allocates memory for arrays in a disprm struct and sets all
00471 * members of the struct to default values.
00472 *
00473 \star PLEASE NOTE: every disprm struct must be initialized by disinit(), possibly
00474 \star repeatedly. On the first invokation, and only the first invokation,
00475 * disprm::flag must be set to -1 to initialize memory management, regardless
00476 \star of whether disinit() will actually be used to allocate memory.
00477 *
00478 * Given:
00479 *
         alloc
                   int
                              If true, allocate memory unconditionally for arrays in
00480 *
                              the disprm struct.
00481 *
00482 *
                              If false, it is assumed that pointers to these arrays
00483 *
                              have been set by the user except if they are null
00484 *
                              pointers in which case memory will be allocated for
00485 *
                               them regardless. (In other words, setting alloc true
00486 *
                              saves having to initalize these pointers to zero.)
00487 *
         naxis
                              The number of world coordinate axes, used to determine
00489 *
                              array sizes.
00490 *
00491 \star Given and returned:
00492 *
         dis
                   struct disprm*
00493
                              Distortion function parameters. Note that, in order
00494 *
                              to initialize memory management disprm::flag must be
00495 *
                              set to -1 when dis is initialized for the first time
00496 *
                               (memory leaks may result if it had already been
00497 *
                              initialized).
00498 *
00499 * Given:
00500 * ndpmax
                              The number of DPja or DQia keywords to allocate space
                    int
                                    If set to -1, the value of the global variable
00501 *
00502 *
                              NDPMAX will be used. This is potentially
00503 *
                              thread-unsafe if disndp() is being used dynamically to
00504 *
                              alter its value.
00505 *
00506 * Function return value:
00507 *
                              Status return value:
00508 *
                                0: Success.
00509 *
                                1: Null disprm pointer passed.
00510 *
                                2: Memory allocation failed.
00511 *
00512 *
                              For returns > 1, a detailed error message is set in
                              disprm::err if enabled, see wcserr_enable().
00514 *
00515 *
00516 \star discpy() - Copy routine for the disprm struct
00517
00518 * discpy() does a deep copy of one disprm struct to another, using disinit()
```

```
00519 * to allocate memory unconditionally for its arrays if required.
                                                                          Only the
00520 * "information to be provided" part of the struct is copied; a call to
00521 * disset() is required to initialize the remainder.
00522 *
00523 * Given:
00524 *
                              If true, allocate memory unconditionally for arrays in
                    int
          alloc
                               the destination. Otherwise, it is assumed that
00525 *
00526 *
                               pointers to these arrays have been set by the user
00527 *
                               except if they are null pointers in which case memory
00528 *
                               will be allocated for them regardless.
00529 *
00530 *
         dissrc const struct disprm*
00531 *
                              Struct to copy from.
00532 *
00533 * Given and returned:
00534 * disdst struct disprm*
                               Struct to copy to. disprm::flag should be set to -1
00535 *
                              if disdst was not previously initialized (memory leaks may result if it was previously initialized).
00536 *
00538 *
00539 * Function return value:
00540 *
                    int
                               Status return value:
00541 *
                                 0: Success.
00542 *
                                 1: Null disprm pointer passed.
00543 *
                                 2: Memory allocation failed.
00544
00545 *
                               For returns > 1, a detailed error message is set in
00546 *
                               disprm::err if enabled, see wcserr_enable().
00547 *
00548 *
00549 * disfree() - Destructor for the disprm struct
00550 *
00551 \star disfree() frees memory allocated for the disprm arrays by disinit().
00552 \star disinit() keeps a record of the memory it allocates and disfree() will only
00553 * attempt to free this.
00554 *
00555 * PLEASE NOTE: disfree() must not be invoked on a disprm struct that was not
00556 * initialized by disinit().
00557 *
00558 * Given:
00559 *
                    struct disprm*
         dis
00560 *
                               Distortion function parameters.
00561 *
00562 * Function return value:
00563 *
                    int
                              Status return value:
00564 *
                                 0: Success.
00565 *
                                 1: Null disprm pointer passed.
00566 *
00567 *
00568 * dissize() - Compute the size of a disprm struct
00570 \star dissize() computes the full size of a disprm struct, including allocated
00571 * memory.
00572 *
00573 * Given:
00574 *
                   const struct disprm*
          dis
00575 *
                              Distortion function parameters.
00576 *
                               If NULL, the base size of the struct and the allocated
00577 *
00578 *
                               size are both set to zero.
00579 *
00580 * Returned:
00581 *
                    int[2]
                              The first element is the base size of the struct as
          sizes
00582 *
                               returned by sizeof(struct disprm). The second element
                               is the total allocated size, in bytes, assuming that
00583 *
00584 *
                               the allocation was done by disini(). This figure
00585 *
                               includes memory allocated for members of constituent
00586 *
                               structs, such as disprm::dp.
00587 *
00588
                               It is not an error for the struct not to have been set
00589 *
                               up via tabset(), which normally results in additional
00590 +
                               memory allocation.
00591 *
00592 * Function return value:
00593 *
                             Status return value:
                   int
00594 *
                                 0: Success.
00595 *
00596 *
00597 * disenq() - enquire about the state of a disprm struct
00598 *
00599 \star diseng() may be used to obtain information about the state of a disprm
00600 \star struct. The function returns a true/false answer for the enquiry asked.
00601 *
00602 * Given:
00603 *
         dis
                    const struct disprm*
00604 *
                              Distortion function parameters.
00605 *
```

```
Enquiry according to the following parameters:
            enquiry int
                                       DISENQ_MEM: memory in the struct is being managed by
00607 *
00608 *
                                                     WCSLIB (see disinit()).
00609 *
                                       {\tt DISENQ\_SET:} the struct has been set up by disset().
00610 *
                                      DISENQ_BYP: the struct is in bypass mode (see
00611 *
                                                     disset()).
                                    These may be combined by logical OR, e.g. DISENQ_MEM | DISENQ_SET. The enquiry result will be
00612
00613
00614 *
                                    the logical AND of the individual results.
00615 *
00616 * Function return value:
00617 *
                       int
                                    Enquiry result:
00618 *
                                       0: No.
00619 *
                                       1: Yes.
00620 *
00621 *
00622 * disprt() - Print routine for the disprm struct
00623 *
00624 \star disprt() prints the contents of a disprm struct using wcsprintf(). Mainly
00625 * intended for diagnostic purposes.
00626 *
00627 * Given:
00628 * dis
                      const struct disprm*
00629 *
                                    Distortion function parameters.
00630 *
00631 * Function return value:
00632 *
                                    Status return value:
                        int
00633 *
                                       0: Success.
00634 *
                                       1: Null disprm pointer passed.
00635 *
00636
00637 * disperr() - Print error messages from a disprm struct
00638 *
00639 \star disperr() prints the error message(s) (if any) stored in a disprm struct.
00640 \star If there are no errors then nothing is printed. It uses wcserr_prt(), q.v.
00641 *
00642 * Given:
00643 * dis
                      const struct disprm*
00644 *
                                    Distortion function parameters.
00645 *
00646 *
           prefix
                       const char *
                                    If non-NULL, each output line will be prefixed with
00647 *
00648 *
                                    this string.
00649 *
00650 * Function return value:
00651 *
                        int
                                    Status return value:
00652 *
                                       0: Success.
00653 *
                                       1: Null disprm pointer passed.
00654 *
00655 *
00656 * dishdo() - write FITS headers using TPD
00657 *
00658 \star dishdo() sets a flag that tells wcshdo() to write FITS headers in the form
00659 \star of the TPD translation used internally. Normally SIP and TPV would be 00660 \star written in their native form if at all possible.
00661 *
00662 * Given and returned:
00663 * dis struct disprm*
00664 *
                                    Distortion function parameters.
00665 *
00666 * Function return value:
00667 *
                                    Status return value:
                        int
00668 *
                                       0: Success.
00669 *
                                       1: Null disprm pointer passed.
00670 *
                                       3: No TPD translation.
00671 *
00672 *
00673 \star disset() - Setup routine for the disprm struct
00674 * --
00675 \star disset(), sets up the disprm struct according to information supplied within
00676 \star it - refer to the explanation of disprm::flag.
00677
00678 * Note that this routine need not be called directly; it will be invoked by 00679 * disp2x() and disx2p() if the disprm::flag is anything other than a
00680 * predefined magic value.
00681 *
00682 * disset() normally operates regardless of the value of disprm::flag; i.e.
00683 * even if a struct was previously set up it will be reset unconditionally.
00684 * However, a disprm struct may be put into "bypass" mode by invoking disset()
00685 * initially with disprm::flag == 1 (rather than 0). disset() will return
00686 * immediately if invoked on a struct in that state. To take a struct out of
00687 * bypass mode, simply reset disprm::flag to zero. See also diseng().
00688 *
00689 * Given and returned:
00690 *
           dis
                      struct disprm*
                                    Distortion function parameters.
00691 *
00692 *
```

```
00693 * Function return value:
                                 Status return value:
                     int
00695 *
                                   0: Success.
00696 *
                                   1: Null disprm pointer passed.
00697 *
                                   2: Memory allocation failed.
00698 *
                                   3: Invalid parameter.
00699
00700 *
                                 For returns > 1, a detailed error message is set in
00701 *
                                 disprm::err if enabled, see wcserr_enable().
00702 *
00703 *
00704 \star disp2x() - Apply distortion function
00705 *
00706 \star disp2x() applies the distortion functions. By definition, the distortion
00707 \star is in the pixel-to-world direction.
00708
00709 \star Depending on the point in the algorithm chain at which it is invoked,
00710 \star disp2x() may transform pixel coordinates to corrected pixel coordinates, or
00711 * intermediate pixel coordinates to corrected intermediate pixel coordinates,
00712 \star or image coordinates to corrected image coordinates.
00713 *
00714 *
00715 * Given and returned:
00716 * dis
                     struct disprm*
00717 *
                                 Distortion function parameters.
00718 *
00719 * Given:
00720 * rawcrd
                   const double[naxis]
00721 *
                                Array of coordinates.
00722 *
00723 * Returned:
00724 *
                     double[naxis]
          discrd
00725 *
                                Array of coordinates to which the distortion functions
00726 *
                                 have been applied.
00727 *
00728 * Function return value:
00729 *
                                 Status return value:
                     int
00730 *
                                   0: Success.
00731 *
                                   1: Null disprm pointer passed.
00732 *
                                   2: Memory allocation failed.
00733 *
                                   3: Invalid parameter.
00734 *
                                   4: Distort error.
00735 *
00736 *
                                 For returns > 1, a detailed error message is set in
00737 *
                                 disprm::err if enabled, see wcserr_enable().
00738 *
00739 *
00740 * disx2p() - Apply de-distortion function
00741 *
00742 * disx2p() applies the inverse of the distortion functions. By definition,
00743 * the de-distortion is in the world-to-pixel direction.
00744 *
00745 \star Depending on the point in the algorithm chain at which it is invoked,
00746 \star disx2p() may transform corrected pixel coordinates to pixel coordinates, or 00747 \star corrected intermediate pixel coordinates to intermediate pixel coordinates,
00748 * or corrected image coordinates to image coordinates.
00749 *
00750 * disx2p() iteratively solves for the inverse using disp2x(). It assumes
00751 * that the distortion is small and the functions are well-behaved, being
00752 \star continuous and with continuous derivatives. Also that, to first order
00753 \star in the neighbourhood of the solution, discrd[j] \sim= a + b\starrawcrd[j], i.e. 00754 \star independent of rawcrd[i], where i != j. This is effectively equivalent to 00755 \star assuming that the distortion functions are separable to first order.
00756 * Furthermore, a is assumed to be small, and b close to unity.
00757 *
00758 * If disprm::disx2p() is defined, then disx2p() uses it to provide an initial
00759 \star estimate for its more precise iterative inversion.
00760 *
00761 * Given and returned:
00762 *
          dis struct disprm*
00763 *
                                 Distortion function parameters.
00764 *
00765 * Given:
00766 * discrd
                      const double[naxis]
00767 *
                                Array of coordinates.
00768 *
00769 * Returned:
00770 * rawcrd double[naxis]
00771 *
                                 Array of coordinates to which the inverse distortion
00772 *
                                 functions have been applied.
00773 *
00774 * Function return value:
00775 *
                     int
                                 Status return value:
00776 *
                                   0: Success.
00777 *
                                   1: Null disprm pointer passed.
00778 *
                                   2: Memory allocation failed.3: Invalid parameter.
00779 *
```

```
5: De-distort error.
00781 *
00782 *
                               For returns > 1, a detailed error message is set in
                               disprm::err if enabled, see wcserr_enable().
00783 *
00784 *
00785
00786 * diswarp() - Compute measures of distortion
00787 *
00788 \star diswarp() computes various measures of the distortion over a specified range
00789 * of coordinates.
00790 *
00791 \star For prior distortions, the measures may be interpreted simply as an offset
00792 * in pixel coordinates.
                               For sequent distortions, the interpretation depends
00793 * on the nature of the linear transformation matrix (PCi_ja or CDi_ja).
00794 \star the latter introduces a scaling, then the measures will also be scaled.
00795 \star Note also that the image domain, which is rectangular in pixel coordinates,
00796 \star may be rotated, skewed, and/or stretched in intermediate pixel coordinates,
00797 \star and in general cannot be defined using pixblc[] and pixtrc[].
00799 \star PLEASE NOTE: the measures of total distortion may be essentially meaningless
00800 * if there are multiple sequent distortions with different scaling.
00801 *
00802 * See also linwarp().
00803 *
00804 * Given and returned:
00805 * dis
                   struct disprm*
00806 *
                               Distortion function parameters.
00807
00808 * Given:
00809 *
         pixblc
                    const double[naxis]
00810
                               Start of the range of pixel coordinates (for prior
00811 *
                               distortions), or intermediate pixel coordinates (for
00812 *
                               sequent distortions). May be specified as a NULL
00813 *
                               pointer which is interpreted as (1,1,\ldots).
00814 *
         pixtrc
00815 *
                    const double[naxis]
00816 *
                               End of the range of pixel coordinates (prior) or
                               intermediate pixel coordinates (sequent).
00818 *
00819 *
          pixsamp
                   const double[naxis]
00820 *
                               If positive or zero, the increment on the particular
00821 *
                               axis, starting at pixblc[]. Zero is interpreted as a
unit increment. pixsamp may also be specified as a
00822 *
                               NULL pointer which is interpreted as all zeroes, i.e.
00823 *
00824
                               unit increments on all axes.
00825 *
00826 *
                               If negative, the grid size on the particular axis (the
00827
                               absolute value being rounded to the nearest integer).
                               For example, if pixsamp is (-128.0, -128.0, \ldots) then
00828 *
                               each axis will be sampled at 128 points between
00829
00830 *
                               pixblc[] and pixtrc[] inclusive.
                                                                  Use caution when
00831 *
                               using this option on non-square images.
00832 *
00833 * Returned:
                    int*
                              The number of pixel coordinates sampled.
00834 *

00868 *
00869 *
                              Can be specified as a NULL pointer if not required.
00870 *
00871 * Function return value:
00872 *
                               Status return value:
                    int
                                 0: Success.
00874 *
                                 1: Null disprm pointer passed.
                                 2: Memory allocation failed.
00875 *
00876 *
                                 3: Invalid parameter.
00877 *
                                 4: Distort error.
00878 *
00879
00880 * disprm struct - Distortion parameters
00881 *
00882 \star The disprm struct contains all of the information required to apply a set of
00883 * distortion functions. It consists of certain members that must be set by
00884 \star the user ("given") and others that are set by the WCSLIB routines
00885 * ("returned"). While the addresses of the arrays themselves may be set by
00886 \star disinit() if it (optionally) allocates memory, their contents must be set by
00887 * the user.
00888 *
00889 *
         int flag
00890 *
            (Given and returned) This flag must be set to zero (or 1, see disset())
00891 *
            whenever any of the following disprm members are set or changed:
00892 *
00893 *
              - disprm::naxis,
00894 *
              - disprm::dtype,
              - disprm::ndp,
00895 *
00896 *
              - disprm::dp.
00897 *
00898 *
            This signals the initialization routine, disset(), to recompute the
00899 *
            returned members of the disprm struct. disset() will reset flag to
00900 *
            indicate that this has been done.
00901 *
00902 *
            PLEASE NOTE: flag must be set to -1 when disinit() is called for the
00903 *
            first time for a particular disprm struct in order to initialize memory % \left( \frac{1}{2}\right) =\frac{1}{2}\left( \frac{1}{2}\right) 
            management. It must ONLY be used on the first initialization otherwise
00904 *
00905 *
            memory leaks may result.
00906 *
          int naxis
00907 *
00908 *
            (Given or returned) Number of pixel and world coordinate elements.
00909 *
00910 *
            If disinit() is used to initialize the disprm struct (as would normally
00911 *
            be the case) then it will set naxis from the value passed to it as a
00912 *
            function argument.
                                The user should not subsequently modify it.
00913 *
00914 *
          char (*dtype)[72]
            (Given) Pointer to the first element of an array of char[72] containing
00915 *
00916 *
            the name of the distortion function for each axis.
00917 *
00918 *
00919 *
            (Given) The number of entries in the disprm::dp[] array.
00920 *
00921 *
         int ndpmax
00922 *
            (Given) The length of the disprm::dp[] array.
00923 *
00924 *
            ndpmax will be set by disinit() if it allocates memory for disprm::dp[],
00925 *
           otherwise it must be set by the user. See also disndp().
00926 *
00927 *
         struct dpkey dp
00928 *
           (Given) Address of the first element of an array of length ndpmax of
00929 *
            dpkey structs.
00930 *
00931 *
            As a FITS header parser encounters each DPja or DQia keyword it should
00932 *
            load it into a dpkey struct in the array and increment ndp. However,
00933 *
            note that a single disprm struct must hold only DPja or DQia keyvalues,
00934 *
            not both. disset() interprets them as required by the particular
00935 *
            distortion function.
00936 *
00937 *
          double *maxdis
00938 *
            (Given) Pointer to the first element of an array of double specifying
00939 *
            the maximum absolute value of the distortion for each axis computed over
00940 *
            the whole image.
00941 *
00942 *
            It is not necessary to reset the disprm struct (via disset()) when
00943 *
            disprm::maxdis is changed.
00944 *
00945 *
          double totdis
00946 *
            (Given) The maximum absolute value of the combination of all distortion
00947 *
            functions specified as an offset in pixel coordinates computed over the
00948 *
            whole image.
00949 *
00950 *
            It is not necessary to reset the disprm struct (via disset()) when
00951 *
            disprm::totdis is changed.
00952 *
00953 *
         int *docorr
```

```
(Returned) Pointer to the first element of an array of int containing
00955 *
                         flags that indicate the mode of correction for each axis.
00956 *
00957 *
                         If docorr is zero, the distortion function returns the corrected
00958 *
                          coordinates directly. Any other value indicates that the distortion
                          function computes a correction to be added to pixel coordinates (prior
00959 *
                         distortion) or intermediate pixel coordinates (sequent distortion).
00961 *
00962 *
                     int *Nhat
00963 *
                          (Returned) Pointer to the first element of an array of int containing
00964 *
                          the number of coordinate axes that form the independent variables of the
00965 *
                         distortion function for each axis.
00966 *
00967 *
00968 *
                          (Returned) Pointer to the first element of an array of int* containing
00969 *
                         pointers to the first elements of the axis mapping arrays for each axis.
00970 *
00971 *
                          An axis mapping associates the independent variables of a distortion
                         function with the 0-relative image axis number. For example, consider
00973 *
                          an image with a spectrum on the first axis (axis 0), followed by RA
00974 *
                          (axis 1), Dec (axis2), and time (axis 3) axes. For a distortion in
00975 *
                          (RA,Dec) and no distortion on the spectral or time axes, the axis % \left( 1\right) =\left( 1\right) +\left( 1\right) +
00976 *
                         mapping arrays, axmap[j][], would be
00977 *
00978 =
                                                                                  ...no distortion on spectral axis,
                              j=0: [-1, -1, -1, -1]
00979 =
                                 1: [ 1, 2, -1, -1]
2: [ 2, 1, -1, -1]
                                                                                 ...RA distortion depends on RA and Dec,
00980 =
                                                                                  ...Dec distortion depends on Dec and RA,
                                  3: [-1, -1, -1, -1]
00981 =
                                                                                 ...no distortion on time axis,
00982 *
                          where \neg 1 indicates that there is no corresponding independent
00983 *
00984 *
                         variable.
00985 *
00986 *
                     double **offset
00987 *
                          (Returned) Pointer to the first element of an array of double*
00988 *
                          containing pointers to the first elements of arrays of offsets used to
00989 *
                          renormalize the independent variables of the distortion function for
00990 *
                         each axis.
00991 *
00992 *
                          The offsets are subtracted from the independent variables before
00993 *
                         scaling.
00994 *
00995 *
                    double **scale
                         (Returned) Pointer to the first element of an array of double*
00996 *
00997 *
                          containing pointers to the first elements of arrays of scales used to
00998 *
                         renormalize the independent variables of the distortion function for
00999 +
01000 *
01001 *
                        The scale is applied to the independent variables after the offsets are
01002 *
                         subtracted.
01003 *
01004 *
                     int **iparm
01005 *
                         (Returned) Pointer to the first element of an array of int*
01006 *
                          containing pointers to the first elements of the arrays of integer
01007 *
                          distortion parameters for each axis.
01008 *
01009 *
                    double **dparm
01010 *
                        (Returned) Pointer to the first element of an array of double*
                         containing pointers to the first elements of the arrays of floating
01011 *
01012 *
                        point distortion parameters for each axis.
01013 *
01014 *
                    int i naxis
01015 *
                         (Returned) Dimension of the internal arrays (normally equal to naxis).
01016 *
01017 *
01018 *
                         (Returned) The number of distortion functions.
01019 *
01020 *
                     struct wcserr *err
                        (Returned) If enabled, when an error status is returned, this struct
01021 *
01022 *
                         contains detailed information about the error, see wcserr_enable().

```

```
01042 \star dpkey struct - Store for DPja and DQia keyvalues
01043 * -
01044 \star The dpkey struct is used to pass the parsed contents of DPja or DQia
01045 \star keyrecords to disset() via the disprm struct. A disprm struct must hold
01046 * only DPja or DQia keyvalues, not both.
01048 \star All members of this struct are to be set by the user.
01049 *
01050 *
          char field[72]
01051 *
            (Given) The full field name of the record, including the keyword name.
            Note that the colon delimiter separating the field name and the value in
01052 *
01053 *
            record-valued keyvalues is not part of the field name. For example, in
01054 *
            the following:
01055 *
01056 =
              DP3A = 'AXIS.1: 2'
01057 *
01058 *
            the full record field name is "DP3A.AXIS.1", and the record's value
01059 *
            is 2.
01060 *
01061 *
01062 *
            (Given) Axis number (1-relative), i.e. the j in DPja or i in DQia.
01063 *
01064 *
          int type
01065 *
            (Given) The data type of the record's value
             - 0: Integer (stored as an int),
01066 *
01067 *
              - 1: Floating point (stored as a double).
01068 *
01069 *
          union value
           (Given) A union comprised of
01070 *
01071 *
              - dpkev::i,
01072 *
              - dpkey::f,
01073 *
01074 *
            the record's value.
01075 *
01076 *
01077 * Global variable: const char *dis errmsg[] - Status return messages
01079 \star Error messages to match the status value returned from each function.

6.5.1 Detailed Description

The Flexible Image Transport System (FITS), is a data format widely used in astronomy for data interchange and archive. It is described in

```
"Definition of the Flexible Image Transport System (FITS), version 3.0", Pence, W.D., Chiappetti, L., Page, C.G., Shaw, R.A., & Stobie, E. 2010, A&A, 524, A42 - http://dx.doi.org/10.1051/0004-6361/201015362
```

See also http:

fitshdr() is a generic FITS header parser provided to handle keyrecords that are ignored by the WCS header parsers, wcspih() and wcsbth(). Typically the latter may be set to remove WCS keyrecords from a header leaving fitshdr() to handle the remainder.

6.5.2 Macro Definition Documentation

FITSHDR_KEYWORD

```
#define FITSHDR_KEYWORD 0x01
```

Flag bit indicating illegal keyword syntax.

Bit mask for the status flag bit-vector returned by fitshdr() indicating illegal keyword syntax.

FITSHDR KEYVALUE

```
#define FITSHDR_KEYVALUE 0x02
```

Flag bit indicating illegal keyvalue syntax.

Bit mask for the status flag bit-vector returned by fitshdr() indicating illegal keyvalue syntax.

FITSHDR COMMENT

```
#define FITSHDR_COMMENT 0 \times 04
```

Flag bit indicating illegal keycomment syntax.

Bit mask for the status flag bit-vector returned by fitshdr() indicating illegal keycomment syntax.

FITSHDR_KEYREC

```
#define FITSHDR_KEYREC 0x08
```

Flag bit indicating illegal keyrecord.

Bit mask for the status flag bit-vector returned by fitshdr() indicating an illegal keyrecord, e.g. an END keyrecord with trailing text.

FITSHDR_CARD

```
#define FITSHDR_CARD 0x08
```

Deprecated.

Deprecated Added for backwards compatibility, use FITSHDR KEYREC instead.

FITSHDR_TRAILER

```
#define FITSHDR_TRAILER 0x10
```

Flag bit indicating keyrecord following a valid END keyrecord.

Bit mask for the status flag bit-vector returned by fitshdr() indicating a keyrecord following a valid END keyrecord.

KEYIDLEN

```
#define KEYIDLEN (sizeof(struct fitskeyid)/sizeof(int))
```

KEYLEN

```
#define KEYLEN (sizeof(struct fitskey)/sizeof(int))
```

6.5.3 Typedef Documentation

int64

int64

64-bit signed integer data type.

64-bit signed integer data type defined via preprocessor macro WCSLIB_INT64 which may be defined in wcsconfig.h. For example

```
#define WCSLIB_INT64 long long int
```

This is typedef'd in fitshdr.h as

```
#ifdef WCSLIB_INT64
  typedef WCSLIB_INT64 int64;
#else
  typedef int int64[3];
#ensit
```

See fitskey::type.

FITSHDRERR_NULL_POINTER	
FITSHDRERR_MEMORY	
FITSHDRERR_FLEX_PARSER	
FITSHDRERR_DATA_TYPE	

6.5.5 Function Documentation

fitshdr()

FITS header parser routine.

fitshdr() parses a character array containing a FITS header, extracting all keywords and their values into an array of fitskey structs.

Parameters

in	header	Character array containing the (entire) FITS header, for example, as might be obtained conveniently via the CFITSIO routine fits_hdr2str(). Each header "keyrecord" (formerly "card image") consists of exactly 80 7-bit ASCII printing characters in the range 0x20 to 0x7e (which excludes NUL, BS, TAB, LF, FF and CR) especially noting that the keyrecords are NOT null-terminated.
in	nkeyrec	Number of keyrecords in header[].
in	nkeyids	Number of entries in keyids[].
in,out	keyids	While all keywords are extracted from the header, keyids[] provides a convienient way of indexing them. The fitskeyid struct contains three members; fitskeyid::name must be set by the user while fitskeyid::count and fitskeyid::idx are returned by fitshdr(). All matched keywords will have their fitskey::keyno member negated.
out	nreject	Number of header keyrecords rejected for syntax errors.
out	keys	Pointer to an array of nkeyrec fitskey structs containing all keywords and keyvalues extracted from the header. Memory for the array is allocated by fitshdr () and this must be freed by the user. See wcsdealloc().

Returns

Status return value:

- 0: Success.
- 1: Null fitskey pointer passed.
- 2: Memory allocation failed.

- 3: Fatal error returned by Flex parser.
- · 4: Unrecognised data type.

Notes:

- 1. Keyword parsing is done in accordance with the syntax defined by NOST 100-2.0, noting the following points in particular:
 - a Sect. 5.1.2.1 specifies that keywords be left-justified in columns 1-8, blank-filled with no embedded spaces, composed only of the ASCII characters ABCDEFGHJKLMNOPQRSTUVWXYZ0123456789-←
 - **fitshdr**() accepts any characters in columns 1-8 but flags keywords that do not conform to standard syntax.
 - b Sect. 5.1.2.2 defines the "value indicator" as the characters "= " occurring in columns 9 and 10. If these are absent then the keyword has no value and columns 9-80 may contain any ASCII text (but see note 2 for **CONTINUE** keyrecords). This is copied to the comment member of the fitskey struct.
 - c Sect. 5.1.2.3 states that a keyword may have a null (undefined) value if the value/comment field, columns 11-80, consists entirely of spaces, possibly followed by a comment.
 - d Sect. 5.1.1 states that trailing blanks in a string keyvalue are not significant and the parser always removes them. A string containing nothing but blanks will be replaced with a single blank.

 Sect. 5.2.1 also states that a quote character (') in a string value is to be represented by two successive quote characters and the parser removes the repeated quote.
 - e The parser recognizes free-format character (NOST 100-2.0, Sect. 5.2.1), integer (Sect. 5.2.3), and floating-point values (Sect. 5.2.4) for all keywords.
 - f Sect. 5.2.3 offers no comment on the size of an integer keyvalue except indirectly in limiting it to 70 digits. The parser will translate an integer keyvalue to a 32-bit signed integer if it lies in the range 2147483648 to +2147483647, otherwise it interprets it as a 64-bit signed integer if possible, or else a "very long" integer (see fitskey::type).
 - g END not followed by 77 blanks is not considered to be a legitimate end keyrecord.
- 2. The parser supports a generalization of the OGIP Long String Keyvalue Convention (v1.0) whereby strings may be continued onto successive header keyrecords. A keyrecord contains a segment of a continued string if and only if
 - a it contains the pseudo-keyword CONTINUE,
 - b columns 9 and 10 are both blank,
 - c columns 11 to 80 contain what would be considered a valid string keyvalue, including optional keycomment, if column 9 had contained '=',
 - d the previous keyrecord contained either a valid string keyvalue or a valid **CONTINUE** keyrecord.

If any of these conditions is violated, the keyrecord is considered in isolation.

Syntax errors in keycomments in a continued string are treated more permissively than usual; the '/' delimiter may be omitted provided that parsing of the string keyvalue is not compromised. However, the FITSHDR_ \leftarrow COMMENT status bit will be set for the keyrecord (see fitskey::status).

As for normal strings, trailing blanks in a continued string are not significant.

In the OGIP convention "the '&' character is used as the last non-blank character of the string to indicate that the string is (probably) continued on the following keyword". This additional syntax is not required by **fitshdr**(), but if '&' does occur as the last non-blank character of a continued string keyvalue then it will be removed, along with any trailing blanks. However, blanks that occur before the '&' will be preserved.

6.5.6 Variable Documentation

fitshdr_errmsg

```
const char * fitshdr_errmsq[] [extern]
```

Status return messages.

Error messages to match the status value returned from each function.

00096 *
                                4: Unrecognised data type.
00097 *
00098 * Notes:
00099 *
         1: Keyword parsing is done in accordance with the syntax defined by
00100 *
            NOST 100-2.0, noting the following points in particular:
00101 *
00102 *
             a: Sect. 5.1.2.1 specifies that keywords be left-justified in columns
00103 *
                1-8, blank-filled with no embedded spaces, composed only of the
00104 *
               ASCII characters ABCDEFGHJKLMNOPQRSTUVWXYZ0123456789-_
00105 *
00106 *
                00107 *
               that do not conform to standard syntax.
00108 *
00109 *
            b: Sect. 5.1.2.2 defines the "value indicator" as the characters "= " \,
00110 *
                occurring in columns 9 and 10. If these are absent then the
00111 *
                keyword has no value and columns 9-80 may contain any ASCII text
                (but see note 2 for CONTINUE keyrecords). This is copied to the
00112 *
               comment member of the fitskey struct.
00113 *
00114 *
00115 *
            c: Sect. 5.1.2.3 states that a keyword may have a null (undefined)
00116 *
                value if the value/comment field, columns 11-80, consists entirely
00117 *
               of spaces, possibly followed by a comment.
00118 *
00119 *
             d: Sect. 5.1.1 states that trailing blanks in a string keyvalue are
00120 *
               not significant and the parser always removes them. A string
               containing nothing but blanks will be replaced with a single
00121 *
00122 *
               blank.
00123 *
00124 *
               Sect. 5.2.1 also states that a quote character (^{\prime}) in a string
00125 *
               value is to be represented by two successive quote characters and
00126 *
               the parser removes the repeated quote.
00127 *
00128 *
             e: The parser recognizes free-format character (NOST 100-2.0,
00129 *
                Sect. 5.2.1), integer (Sect. 5.2.3), and floating-point values
00130 *
                (Sect. 5.2.4) for all keywords.
00131 *
             f: Sect. 5.2.3 offers no comment on the size of an integer keyvalue
00132 *
               except indirectly in limiting it to 70 digits. The parser will
00133 *
                translate an integer keyvalue to a 32-bit signed integer if it
00134 *
00135 *
                lies in the range -2147483648 to +2147483647, otherwise it
00136 *
                interprets it as a 64-bit signed integer if possible, or else a
               "very long" integer (see fitskey::type).
00137 *
00138 *
00139 *
            g: END not followed by 77 blanks is not considered to be a legitimate
00140 *
               end keyrecord.
00141 *
00142 *
         2: The parser supports a generalization of the OGIP Long String Keyvalue
00143 *
             Convention (v1.0) whereby strings may be continued onto successive
00144 *
             header keyrecords. A keyrecord contains a segment of a continued
00145 *
             string if and only if
00146 *
00147 *
            a: it contains the pseudo-keyword CONTINUE,
00148 *
00149 *
            b: columns 9 and 10 are both blank,
00150 *
00151 *
            c: columns 11 to 80 contain what would be considered a valid string
```

```
keyvalue, including optional keycomment, if column 9 had contained
00153 *
00154 *
00155 *
              d: the previous keyrecord contained either a valid string keyvalue or
00156 *
                a valid CONTINUE keyrecord.
00157 *
00158 *
              If any of these conditions is violated, the keyrecord is considered in
00159 *
00160 *
              Syntax errors in keycomments in a continued string are treated more permissively than usual; the ^\prime\prime^\prime delimiter may be omitted provided that
00161 *
00162 *
00163 *
              parsing of the string keyvalue is not compromised. However, the
00164 *
              FITSHDR_COMMENT status bit will be set for the keyrecord (see
00165 *
              fitskey::status).
00166 *
00167 *
              As for normal strings, trailing blanks in a continued string are not
00168 *
              significant.
00169 *
              In the OGIP convention "the '\&' character is used as the last non-blank
00171 *
              character of the string to indicate that the string is (probably)
              continued on the following keyword". This additional syntax is not required by fitshdr(), but if '&' does occur as the last non-blank
00172 *
00173 *
              character of a continued string keyvalue then it will be removed, along with any trailing blanks. However, blanks that occur before the '&'
00174 *
00175 *
00176 *
              will be preserved.
00177 *
00178 *
00179 * fitskeyid struct - Keyword indexing
00180 *
00181 * fitshdr() uses the fitskeyid struct to return indexing information for
00182 * specified keywords. The struct contains three members, the first of which,
00183 * fitskeyid::name, must be set by the user with the remainder returned by
00184 * fitshdr().
00185 *
00186 *
          char name[12]:
            (Given) Name of the required keyword. This is to be set by the user; the '.' character may be used for wildcarding. Trailing blanks will be
00187 *
00188 *
             replaced with nulls.
00190 *
00191 *
00192 *
             (Returned) The number of matches found for the keyword.
00193 *
00194 *
          int idx[2]:
00195 *
            (Returned) Indices into keys[], the array of fitskey structs returned by
00196 *
             fitshdr(). Note that these are 0-relative array indices, not keyrecord
00197 *
00198 *
00199 *
            If the keyword is found in the header the first index will be set to the
00200 *
            array index of its first occurrence, otherwise it will be set to -1.
00201 *
00202 *
             If multiples of the keyword are found, the second index will be set to
00203 *
            the array index of its last occurrence, otherwise it will be set to -1.
00204 *
00205 *
00206 * fitskey struct - Keyword/value information
00207 *
00208 \star fitshdr() returns an array of fitskey structs, each of which contains the
00209 \star result of parsing one FITS header keyrecord. All members of the fitskey
00210 * struct are returned by fitshdr(), none are given by the user.
00211 *
00212 *
             (Returned) Keyrecord number (1-relative) in the array passed as input to
00213 *
00214 *
             fitshdr().
                          This will be negated if the keyword matched any specified in
00215 *
            the keyids[] index.
00216 *
00217 *
          int keyid
00218 *
             (Returned) Index into the first entry in keyids[] with which the
00219 *
            keyrecord matches, else -1.
00220 *
00221 *
00222 *
             (Returned) Status flag bit-vector for the header keyrecord employing the
00223 *
             following bit masks defined as preprocessor macros:
00224 *
               - FITSHDR KEYWORD:
00225 *
                                       Illegal keyword syntax.
00226 *
               - FITSHDR_KEYVALUE:
                                       Illegal keyvalue syntax.
00227 *
               - FITSHDR_COMMENT:
                                        Illegal keycomment syntax.
00228 *
               - FITSHDR_KEYREC:
                                       Illegal keyrecord, e.g. an END keyrecord with
                                       trailing text
00229 *
               - FITSHDR TRAILER:
                                       Keyrecord following a valid END keyrecord.
00230 *
00231 *
            The header keyrecord is syntactically correct if no bits are set.
00232 *
00234 *
00235 *
             (Returned) Keyword name, null-filled for keywords of less than eight
00236 *
             characters (trailing blanks replaced by nulls).
00237 *
00238 *
            Use
```

6.6 fitshdr.h 147

```
00239 *
00240 =
               sprintf(dst, "%.8s", keyword)
00241 *
00242 *
            to copy it to a character array with null-termination, or
00243 *
00244 =
               sprintf(dst, "%8.8s", keyword)
00246 *
             to blank-fill to eight characters followed by null-termination.
00247 *
00248 *
00249 *
             (Returned) Keyvalue data type:
00250 *
              - 0: No keyvalue (both the value and type are undefined).
00251 *
               - 1: Logical, represented as int.
00252 *
               - 2: 32-bit signed integer.
00253 *
               - 3: 64-bit signed integer (see below).
00254 *
               - 4: Very long integer (see below)
               - 5: Floating point (stored as double)
00255 *
00256 *
               - 6: Integer complex (stored as double[2]).
               - 7: Floating point complex (stored as double[2]).
                - 8: String.
00258 *
00259 *
               - 8+10*n: Continued string (described below and in fitshdr() note 2).
00260 *
00261 *
             A negative type indicates that a syntax error was encountered when
00262 *
             attempting to parse a keyvalue of the particular type.
00263 *
00264 *
             Comments on particular data types:
00265 *
                 - 64-bit signed integers lie in the range
00266 *
00267 =
                    (-9223372036854775808 \le int64 < -2147483648) ||
                              (+2147483647 < int64 <= +9223372036854775807)
00268 =
00269 *
00270 *
                 A native 64-bit data type may be defined via preprocessor macro WCSLIB_INT64 defined in wcsconfig.h, e.g. as 'long long int'; this will be typedef'd to 'int64' here. If WCSLIB_INT64 is not set, then
00271 *
00272 *
00273 *
                  int64 is typedef'd to int[3] instead and fitskey::keyvalue is to be
00274 *
                  computed as
00275 *
00276 =
                   ((keyvalue.k[2]) * 1000000000 +
00277 =
                      keyvalue.k[1]) * 1000000000 +
00278 =
                      keyvalue.k[0]
00279 *
00280 *
                 and may reported via
00281 *
00282 =
                    if (keyvalue.k[2]) {
                      printf("%d%09d%09d", keyvalue.k[2], abs(keyvalue.k[1]),
00283 =
00284 =
                                               abs(keyvalue.k[0]));
00285 =
                     } else {
                       printf("%d%09d", keyvalue.k[1], abs(keyvalue.k[0]));
00286 =
                     }
00287 =
00288 *
00289 *
                  where keyvalue.k[0] and keyvalue.k[1] range from -999999999 to
00290 *
                  +9999999999.
00291 *
               - Very long integers, up to 70 decimal digits in length, are encoded in keyvalue.1 as an array of int[8], each of which stores 9 decimal
00292 *
00293 *
00294 *
                 digits. fitskey::keyvalue is to be computed as
00295 *
00296 =
                    (((((((keyvalue.1[7]) * 1000000000 +
00297 =
                            keyvalue.1[6]) * 1000000000 +
                            keyvalue.1[5]) * 1000000000 +
00298 =
                            keyvalue.1[4]) * 1000000000 +
00299 =
                            keyvalue.1[3]) * 1000000000 +
keyvalue.1[2]) * 1000000000 +
00300 =
00301 =
00302 =
                            keyvalue.1[1]) * 1000000000 +
00303 =
                            keyvalue.1[0]
00304 *
00305 *
                - Continued strings are not reconstructed, they remain split over
00306 *
                 successive fitskey structs in the keys[] array returned by fitshdr(). fitskey::keyvalue data type, 8 + 10n, indicates the
00307 *
00308 *
                 segment number, n, in the continuation.
00309 *
00310 *
          int padding
00311 *
             (An unused variable inserted for alignment purposes only.)
00312 *
00313 *
          union keyvalue
00314 *
             (Returned) A union comprised of
00315 *
00316 *
               - fitskey::i,
00317 *
               - fitskey::k,
00318 *
               - fitskey::1,
00319 *
               - fitskey::f,
               - fitskey::c,
00320 *
               - fitskey::s,
00321 *
00322 *
00323 *
             used by the fitskey struct to contain the value associated with a
00324 *
             keyword.
00325 *
```

```
00326 *
          int i
00327 *
           (Returned) Logical (fitskey::type == 1) and 32-bit signed integer
00328 *
            (fitskey::type == 2) data types in the fitskey::keyvalue union.
00329 *
00330 *
00331 *
            (Returned) 64-bit signed integer (fitskey::type == 3) data type in the
00332 *
            fitskey::keyvalue union.
00333 *
00334 *
          int 1[8]
00335 *
            (Returned) Very long integer (fitskey::type == 4) data type in the
00336 *
            fitskey::keyvalue union.
00337 *
00338 *
00339 *
            (Returned) Floating point (fitskey::type == 5) data type in the
00340 *
            fitskey::keyvalue union.
00341 *
00342 *
          double c[2]
00343 *
            (Returned) Integer and floating point complex (fitskey::type == 6 || 7)
            data types in the fitskey::keyvalue union.
00345 *
00346 *
00347 *
            (Returned) Null-terminated string (fitskey::type == 8) data type in the
00348 *
            fitskey::keyvalue union.
00349 *
00350 *
          int ulen
00351 *
           (Returned) Where a keycomment contains a units string in the standard
00352 *
            form, e.g. [m/s], the ulen member indicates its length, inclusive of
00353 *
           square brackets. Otherwise ulen is zero.
00354 *
00355 *
          char comment[84]
00356 *
           (Returned) Keycomment, i.e. comment associated with the keyword or, for
00357 *
            keyrecords rejected because of syntax errors, the compete keyrecord
00358 *
            itself with null-termination.
00359 *
00360 *
            Comments are null-terminated with trailing spaces removed. Leading
            spaces are also removed from keycomments (i.e. those immediately following the ^\prime\prime^\prime character), but not from COMMENT or HISTORY keyrecords
00361 *
00362 *
            or keyrecords without a value indicator ("= " in columns 9-80).
00363 *
00364 *
00365 *
00366 \star Global variable: const char \starfitshdr_errmsg[] - Status return messages
00367 * --
00368 * Error messages to match the status value returned from each function.
00369 *

6.7 getwcstab.h File Reference

#include <fitsio.h>

Data Structures

struct wtbarr

Extraction of coordinate lookup tables from BINTABLE.

Functions

• int fits_read_wcstab (fitsfile *fptr, int nwtb, wtbarr *wtb, int *status)

FITS 'TAB' table reading routine.

6.7.1 Detailed Description

fits_read_wcstab(), an implementation of a FITS table reading routine for 'TAB' coordinates, is provided for CFITSIO programmers. It has been incorporated into CFITSIO as of v3.006 with the definitions in this file, getwcstab.h, moved into fitsio.h.

fits_read_wcstab() is not included in the WCSLIB object library but the source code is presented here as it may be useful for programmers using an older version of CFITSIO than 3.006, or as a programming template for non-CFITSIO programmers.

6.7.2 Function Documentation

fits read wcstab()

```
int fits_read_wcstab (
    fitsfile * fptr,
    int nwtb,
    wtbarr * wtb,
    int * status )
```

FITS 'TAB' table reading routine.

fits_read_wcstab() extracts arrays from a binary table required in constructing 'TAB' coordinates.

Parameters

in	fptr	Pointer to the file handle returned, for example, by the fits_open_file() routine in CFITSIO.
in	nwtb	Number of arrays to be read from the binary table(s).
in,out	wtb	Address of the first element of an array of wtbarr typedefs. This wtbarr typedef is defined to match the wtbarr struct defined in WCSLIB. An array of such structs returned by the WCSLIB function wcstab() as discussed in the notes below.
out	status	CFITSIO status value.

Returns

CFITSIO status value.

Notes:

In order to maintain WCSLIB and CFITSIO as independent libraries it is not permissible for any CFITSIO library code to include WCSLIB header files, or vice versa. However, the CFITSIO function fits_read_
 — wcstab() accepts an array of wtbarr structs defined in wcs.h within WCSLIB.

The problem therefore is to define the wtbarr struct within fitsio.h without including wcs.h, especially noting that wcs.h will often (but not always) be included together with fitsio.h in an applications program that uses fits_read_wcstab().

The solution adopted is for WCSLIB to define "struct wtbarr" while fitsio.h defines "typedef wtbarr" as an untagged struct with identical members. This allows both wcs.h and fitsio.h to define a wtbarr data type without conflict by virtue of the fact that structure tags and typedef names share different name spaces in C; Appendix A, Sect. A11.1 (p227) of the K&R ANSI edition states that:

```
Identifiers fall into several name spaces that do not interfere with one another; the same identifier may be used for different purposes, even in the same scope, if the uses are in different name spaces. These classes are: objects, functions, typedef names, and enum constants; labels; tags of structures, unions, and enumerations; and members of each structure or union individually.
```

Therefore, declarations within WCSLIB look like

struct wtbarr *w;

while within CFITSIO they are simply wtbarr *w;

As suggested by the commonality of the names, these are really the same aggregate data type. However, in passing a (struct wtbarr *) to fits_read_wcstab() a cast to (wtbarr *) is formally required.

When using WCSLIB and CFITSIO together in C++ the situation is complicated by the fact that typedefs and structs share the same namespace; C++ Annotated Reference Manual, Sect. 7.1.3 (p105). In that case the wtbarr struct in wcs.h is renamed by preprocessor macro substitution to wtbarr_s to distinguish it from the typedef defined in fitsio.h. However, the scope of this macro substitution is limited to wcs.h itself and CFITSIO programmer code, whether in C++ or C, should always use the wtbarr typedef.

00046 *
00047 * Given:
00048 * fptr
                    fitsfile *
00049 *
                                Pointer to the file handle returned, for example, by
00050 *
                                the fits_open_file() routine in CFITSIO.
00051 *
00052 *
                                Number of arrays to be read from the binary table(s).
00053 *
00054 * Given and returned:
00055 *
          wtb
                    wtbarr * Address of the first element of an array of wtbarr
                                typedefs. This wtbarr typedef is defined to match the wtbarr struct defined in WCSLIB. An array of such
00056 *
00057 *
00058 *
                                structs returned by the WCSLIB function wcstab() as
00059 *
                                discussed in the notes below.
00060 *
00061 * Returned:
00062 *
                             CFITSIO status value.
         status
                     int *
00063 *
00064 * Function return value:
00065 *
                                CFITSIO status value.
00066 *
00067 * Notes:
00068 *
          1: In order to maintain WCSLIB and CFITSIO as independent libraries it is
             not permissible for any CFITSIO library code to include WCSLIB header files, or vice versa. However, the CFITSIO function fits_read_wcstab()
00069 *
             accepts an array of wtbarr structs defined in wcs.h within WCSLIB.
00071 *
00072 *
00073 *
              The problem therefore is to define the wtbarr struct within fitsio.h
00074 *
             without including wcs.h, especially noting that wcs.h will often (but not always) be included together with fitsio.h in an applications \frac{1}{2}
00075 *
00076 *
             program that uses fits_read_wcstab().
00077 *
00078 *
              The solution adopted is for WCSLIB to define "struct wtbarr" while
00079 *
              fitsio.h defines "typedef wtbarr" as an untagged struct with identical
              members. This allows both wcs.h and fitsio.h to define a wtbarr data
00080 *
00081 *
              type without conflict by virtue of the fact that structure tags and
00082 *
              typedef names share different name spaces in C; Appendix A, Sect. All.1
00083 *
             (p227) of the K&R ANSI edition states that:
```

```
00084 *
00085 =
                Identifiers fall into several name spaces that do not interfere with
00086 =
                one another; the same identifier may be used for different purposes,
00087 =
                even in the same scope, if the uses are in different name spaces.
00088 =
                These classes are: objects, functions, typedef names, and enum constants; labels; tags of structures, unions, and enumerations; and
00089 =
                members of each structure or union individually.
00090 =
00091 *
00092 *
              Therefore, declarations within WCSLIB look like
00093 *
00094 =
                struct wtbarr *w:
00095 *
00096 *
              while within CFITSIO they are simply
00097 *
00098 =
                wtbarr *w;
00099 *
              As suggested by the commonality of the names, these are really the same aggregate data type. However, in passing a (struct wtbarr \star) to fits_read_wcstab() a cast to (wtbarr \star) is formally required.
00100 *
00101 *
00102 *
00103 *
00104 *
              When using WCSLIB and CFITSIO together in C++ the situation is
00105 *
              complicated by the fact that typedefs and structs share the same
              namespace; C++ Annotated Reference Manual, Sect. 7.1.3 (p105). In that
00106 *
00107 *
              case the wtbarr struct in wcs.h is renamed by preprocessor macro
00108 *
              substitution to wtbarr_s to distinguish it from the typedef defined in
              fitsio.h. However, the scope of this macro substitution is limited to
00109 *
00110 *
              wcs.h itself and CFITSIO programmer code, whether in C++ or C, should
00111 *
              always use the wtbarr typedef.
00112 *
00113 *
00114 * wtbarr typedef
00115 *
00116 \star The wtbarr typedef is defined as a struct containing the following members:
00117 *
00118 *
00119 *
             Image axis number.
00120 *
00121 *
          int m
00122 *
            Array axis number for index vectors.

```

Functions

• int linini (int alloc, int naxis, struct linprm *lin)

Default constructor for the linprm struct.

• int lininit (int alloc, int naxis, struct linprm *lin, int ndpmax)

Default constructor for the linprm struct.

• int lindis (int sequence, struct linprm *lin, struct disprm *dis)

Assign a distortion to a linprm struct.

• int lindist (int sequence, struct linprm *lin, struct disprm *dis, int ndpmax)

Assign a distortion to a linprm struct.

• int lincpy (int alloc, const struct linprm *linsrc, struct linprm *lindst)

Copy routine for the linprm struct.

• int linfree (struct linprm *lin)

Destructor for the linprm struct.

• int linsize (const struct linprm *lin, int sizes[2])

Compute the size of a linprm struct.

int linenq (const struct linprm *lin, int enquiry)

enquire about the state of a linprm struct.

int linprt (const struct linprm *lin)

Print routine for the linprm struct.

int linperr (const struct linprm *lin, const char *prefix)

Print error messages from a linprm struct.

• int linset (struct linprm *lin)

Setup routine for the linprm struct.

• int linp2x (struct linprm *lin, int ncoord, int nelem, const double pixcrd[], double imgcrd[])

Pixel-to-world linear transformation.

int linx2p (struct linprm *lin, int ncoord, int nelem, const double imgcrd[], double pixcrd[])

World-to-pixel linear transformation.

• int linwarp (struct linprm *lin, const double pixblc[], const double pixtrc[], const double pixsamp[], int *nsamp, double maxdis[], double *maxtot, double avgdis[], double *avgtot, double rmsdis[], double *rmstot)

Compute measures of distortion.

int matinv (int n, const double mat[], double inv[])

Matrix inversion.

Variables

const char * lin_errmsg []

Status return messages.

6.9.1 Detailed Description

Routines in this suite apply the linear transformation defined by the FITS World Coordinate System (WCS) standard, as described in

```
"Representations of world coordinates in FITS",
Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061 (WCS Paper I)
```

These routines are based on the linprm struct which contains all information needed for the computations. The struct contains some members that must be set by the user, and others that are maintained by these routines, somewhat like a C++ class but with no encapsulation.

Six routines, linini(), lininit(), lindis(), lindist() lincpy(), and linfree() are provided to manage the linprm struct, linsize() computes its total size including allocated memory, linenq() returns information about the state of the struct, and linprt() prints its contents.

linperr() prints the error message(s) (if any) stored in a linprm struct, and the disprm structs that it may contain.

A setup routine, linset(), computes intermediate values in the linprm struct from parameters in it that were supplied by the user. The struct always needs to be set up by linset() but need not be called explicitly - refer to the explanation of linprm::flag.

linp2x() and linx2p() implement the WCS linear transformations.

An auxiliary routine, linwarp(), computes various measures of the distortion over a specified range of pixel coordinates.

An auxiliary matrix inversion routine, matinv(), is included. It uses LU-triangular factorization with scaled partial pivoting.

6.9.2 Macro Definition Documentation

LINLEN

```
#define LINLEN (sizeof(struct linprm)/sizeof(int))
```

Size of the linprm struct in int units.

Size of the linprm struct in int units, used by the Fortran wrappers.

linini_errmsg

```
#define linini_errmsg lin_errmsg
```

Deprecated.

LINERR_DEDISTORT	

6.9.4 Function Documentation

linini()

Default constructor for the linprm struct.

linini() is a thin wrapper on **lininit**(). It invokes it with ndpmax set to -1 which causes it to use the value of the global variable NDPMAX. It is thereby potentially thread-unsafe if NDPMAX is altered dynamically via disndp(). Use **lininit**() for a thread-safe alternative in this case.

lininit()

```
int lininit (
          int alloc,
          int naxis,
          struct linprm * lin,
          int ndpmax )
```

Default constructor for the linprm struct.

lininit() allocates memory for arrays in a linprm struct and sets all members of the struct to default values.

PLEASE NOTE: every linprm struct must be initialized by **lininit**(), possibly repeatedly. On the first invokation, and only the first invokation, linprm::flag must be set to -1 to initialize memory management, regardless of whether **lininit**() will actually be used to allocate memory.

Parameters

in	alloc	If true, allocate memory unconditionally for arrays in the linprm struct. If false, it is assumed that pointers to these arrays have been set by the user except if they are null pointers in which case memory will be allocated for them regardless. (In other words, setting alloc true saves having to initalize these pointers to zero.)
in	naxis	The number of world coordinate axes, used to determine array sizes.
in,out	lin	Linear transformation parameters. Note that, in order to initialize memory management linprm::flag should be set to -1 when lin is initialized for the first time (memory leaks may result if it had already been initialized).
in	ndpmax	The number of DPja or DQia keywords to allocate space for. If set to -1, the value of the global variable NDPMAX will be used. This is potentially thread-unsafe if disndp() is being used dynamically to alter its value.

Returns

Status return value:

- · 0: Success.
- 1: Null linprm pointer passed.
- 2: Memory allocation failed.

For returns > 1, a detailed error message is set in linprm::err if enabled, see wcserr enable().

lindis()

Assign a distortion to a linprm struct.

lindis() is a thin wrapper on **lindist**(). It invokes it with ndpmax set to -1 which causes the value of the global variable NDPMAX to be used (by disinit()). It is thereby potentially thread-unsafe if NDPMAX is altered dynamically via disndp(). Use **lindist**() for a thread-safe alternative in this case.

lindist()

```
int lindist (
    int sequence,
    struct linprm * lin,
    struct disprm * dis,
    int ndpmax )
```

Assign a distortion to a linprm struct.

lindist() may be used to assign the address of a disprm struct to linprm::dispre or linprm::disseq. The linprm struct must already have been initialized by lininit().

The disprm struct must have been allocated from the heap (e.g. using malloc(), calloc(), etc.). **lindist**() will immediately initialize it via a call to disini() using the value of linprm::naxis. Subsequently, it will be reinitialized by calls to lininit(), and freed by linfree(), neither of which would happen if the disprm struct was assigned directly.

If the disprm struct had previously been assigned via **lindist**(), it will be freed before reassignment. It is also permissable for a null disprm pointer to be assigned to disable the distortion correction.

Parameters

in	sequence	Is it a prior or sequent distortion?
		1: Prior, the assignment is to linprm::dispre.
		2: Sequent, the assignment is to linprm::disseq.
		Anything else is an error.
in,out	lin	Linear transformation parameters.
in,out	dis	Distortion function parameters.
in	ndpmax	The number of DPja or DQia keywords to allocate space for. If set to -1, the value of
		the global variable NDPMAX will be used. This is potentially thread-unsafe if disndp() is being used dynamically to alter its value.

Returns

Status return value:

- 0: Success.
- 1: Null linprm pointer passed.
- · 4: Invalid sequence.

lincpy()

Copy routine for the linprm struct.

lincpy() does a deep copy of one linprm struct to another, using lininit() to allocate memory for its arrays if required. Only the "information to be provided" part of the struct is copied; a call to linset() is required to initialize the remainder.

Parameters

in	alloc	If true, allocate memory for the crpix, pc, and cdelt arrays in the destination. Otherwise, it is assumed that pointers to these arrays have been set by the user except if they are null pointers in which case memory will be allocated for them regardless.
in	linsrc	Struct to copy from.
in,out	lindst	Struct to copy to. linprm::flag should be set to -1 if lindst was not previously initialized (memory leaks may result if it was previously initialized).

Returns

Status return value:

- 0: Success.
- 1: Null linprm pointer passed.
- 2: Memory allocation failed.

For returns > 1, a detailed error message is set in linprm::err if enabled, see wcserr_enable().

linfree()

```
int linfree (
          struct linprm * lin )
```

Destructor for the linprm struct.

linfree() frees memory allocated for the linprm arrays by lininit() and/or linset(). lininit() keeps a record of the memory it allocates and **linfree**() will only attempt to free this.

PLEASE NOTE: linfree() must not be invoked on a linprm struct that was not initialized by lininit().

Parameters

in	lin	Linear transformation parameters.
----	-----	-----------------------------------

Returns

Status return value:

- 0: Success.
- 1: Null linprm pointer passed.

linsize()

Compute the size of a linprm struct.

linsize() computes the full size of a linprm struct, including allocated memory.

Parameters

in	lin	Linear transformation parameters.
		If NULL, the base size of the struct and the allocated size are both set to zero.
out	sizes	The first element is the base size of the struct as returned by sizeof(struct linprm).
		The second element is the total size of memory allocated in the struct, in bytes, assuming that
		the allocation was done by lininit(). This figure includes memory allocated for members of
		constituent structs, * such as linprm::dispre.
		It is not an error for the struct not to have been set up via linset(), which normally results in
		additional memory allocation.

Returns

Status return value:

• 0: Success.

linenq()

enquire about the state of a linprm struct.

linenq() may be used to obtain information about the state of a linprm struct. The function returns a true/false answer for the enquiry asked.

Parameters

in	lin	Linear transformation parameters.
in	enquiry	Enquiry according to the following parameters:
		LINENQ_MEM: memory in the struct is being managed by WCSLIB (see lininit()).
		LINENQ_SET: the struct has been set up by linset().
		 LINENQ_BYP: the struct is in bypass mode (see linset()).
		These may be combined by logical OR, e.g. LINENQ_MEM LINENQ_SET. The enquiry result will be the logical AND of the individual results.

Returns

Enquiry result:

- 0: No.
- 1: Yes.

linprt()

```
int linprt ( {\tt const\ struct\ linprm\ *\ lin\ )}
```

Print routine for the linprm struct.

linprt() prints the contents of a linprm struct using wcsprintf(). Mainly intended for diagnostic purposes.

Parameters

in	lin	Linear transformation parameters.
----	-----	-----------------------------------

Returns

Status return value:

- 0: Success.
- 1: Null linprm pointer passed.

linperr()

Print error messages from a linprm struct.

linperr() prints the error message(s) (if any) stored in a linprm struct, and the disprm structs that it may contain. If there are no errors then nothing is printed. It uses wcserr prt(), q.v.

Parameters

in	lin	Coordinate transformation parameters.
in	prefix	If non-NULL, each output line will be prefixed with this string.

Returns

Status return value:

- · 0: Success.
- 1: Null linprm pointer passed.

linset()

Setup routine for the linprm struct.

linset(), if necessary, allocates memory for the linprm::piximg and linprm::imgpix arrays and sets up the linprm struct according to information supplied within it - refer to the explanation of linprm::flag.

Note that this routine need not be called directly; it will be invoked by linp2x() and linx2p() if the linprm::flag is anything other than a predefined magic value.

linset() normally operates regardless of the value of linprm::flag; i.e. even if a struct was previously set up it will be reset unconditionally. However, a linprm struct may be put into "bypass" mode by invoking **linset**() initially with linprm::flag == 1 (rather than 0). **linset**() will return immediately if invoked on a struct in that state. To take a struct out of bypass mode, simply reset linprm::flag to zero. See also lineng().

Parameters

in, out lin Linear transformation parameters.

Returns

Status return value:

- 0: Success.
- 1: Null linprm pointer passed.
- 2: Memory allocation failed.

- 3: PCi_ja matrix is singular.
- · 4: Failed to initialise distortions.

For returns > 1, a detailed error message is set in linprm::err if enabled, see wcserr_enable().

linp2x()

Pixel-to-world linear transformation.

linp2x() transforms pixel coordinates to intermediate world coordinates.

Parameters

in,out	lin	Linear transformation parameters.
in	ncoord,nelem	The number of coordinates, each of vector length nelem but containing lin.naxis
		coordinate elements.
in	pixcrd	Array of pixel coordinates.
out	imgcrd	Array of intermediate world coordinates.

Returns

Status return value:

- 0: Success.
- 1: Null linprm pointer passed.
- 2: Memory allocation failed.
- 3: PCi_ja matrix is singular.
- 4: Failed to initialise distortions.
- 5: Distort error.

For returns > 1, a detailed error message is set in linprm::err if enabled, see wcserr_enable().

Notes:

1. Historically, the API to linp2x() did not have a stat[] vector because a valid linear transformation should always succeed. However, now that it invokes disp2x() if distortions are present, it does have the potential to fail. Consequently, when distortions are present and a status return (stat[]) is required for each coordinate, then linp2x() should be invoked separately for each of them.

linx2p()

```
int nelem,
const double imgcrd[],
double pixcrd[])
```

World-to-pixel linear transformation.

linx2p() transforms intermediate world coordinates to pixel coordinates.

Parameters 4 6 1

in,out	lin	Linear transformation parameters.
in	ncoord,nelem	The number of coordinates, each of vector length nelem but containing lin.naxis
		coordinate elements.
in	imgcrd	Array of intermediate world coordinates.
out	pixcrd	Array of pixel coordinates. Status return value:
		• 0: Success.
		1: Null linprm pointer passed.
		2: Memory allocation failed.
		• 3: PCi_ja matrix is singular.
		4: Failed to initialise distortions.
		6: De-distort error.
		For returns > 1, a detailed error message is set in linprm::err if enabled, see wcserr_enable().

Notes:

1. Historically, the API to <code>linx2p()</code> did not have a stat[] vector because a valid linear transformation should always succeed. However, now that it invokes <code>disx2p()</code> if distortions are present, it does have the potential to fail. Consequently, when distortions are present and a status return (stat[]) is required for each coordinate, then <code>linx2p()</code> should be invoked separately for each of them.

linwarp()

Compute measures of distortion.

linwarp() computes various measures of the distortion over a specified range of pixel coordinates.

All distortion measures are specified as an offset in pixel coordinates, as given directly by prior distortions. The offset in intermediate pixel coordinates given by sequent distortions is translated back to pixel coordinates by applying the

If all distortions are prior, then linwarp() uses diswarp(), q.v.

Parameters

in,out	lin	Linear transformation parameters plus distortions.
in	pixblc	Start of the range of pixel coordinates (i.e. "bottom left-hand corner" in the conventional FITS image display orientation). May be specified as a NULL pointer which is interpreted as (1,1,).
in	pixtrc	End of the range of pixel coordinates (i.e. "top right-hand corner" in the conventional FITS image display orientation).
in	pixsamp	If positive or zero, the increment on the particular axis, starting at pixblc[]. Zero is interpreted as a unit increment. pixsamp may also be specified as a NULL pointer which is interpreted as all zeroes, i.e. unit increments on all axes. If negative, the grid size on the particular axis (the absolute value being rounded to the nearest integer). For example, if pixsamp is (-128.0,-128.0,) then each axis will be sampled at 128 points between pixblc[] and pixtrc[] inclusive. Use caution when using this option on non-square images.
out	nsamp	The number of pixel coordinates sampled. Can be specified as a NULL pointer if not required.
out	maxdis	For each individual distortion function, the maximum absolute value of the distortion. Can be specified as a NULL pointer if not required.
out	maxtot	For the combination of all distortion functions, the maximum absolute value of the distortion. Can be specified as a NULL pointer if not required.
out	avgdis	For each individual distortion function, the mean value of the distortion. Can be specified as a NULL pointer if not required.
out	avgtot	For the combination of all distortion functions, the mean value of the distortion. Can be specified as a NULL pointer if not required.
out	rmsdis	For each individual distortion function, the root mean square deviation of the distortion. Can be specified as a NULL pointer if not required.
out	rmstot	For the combination of all distortion functions, the root mean square deviation of the distortion. Can be specified as a NULL pointer if not required.

Returns

Status return value:

- 0: Success.
- 1: Null linprm pointer passed.
- 2: Memory allocation failed.
- 3: Invalid parameter.
- 4: Distort error.

matinv()

```
matinv (
    int n,
    const double mat[],
    double inv[])
```

Matrix inversion.

matinv() performs matrix inversion using LU-triangular factorization with scaled partial pivoting.

Parameters

in	n	Order of the matrix ($n \times n$).	
in	mat	Matrix to be inverted, stored as $\max[in+j]$ where i and j are the row and column indices respectively.	
out	inv	Inverse of mat with the same storage convention.	

Returns

Status return value:

- · 0: Success.
- · 2: Memory allocation failed.
- · 3: Singular matrix.

6.9.5 Variable Documentation

lin_errmsg

```
const char * lin_errmsg[] [extern]
```

Status return messages.

Error messages to match the status value returned from each function.

                                 saves having to initalize these pointers to zero.)
00092 *
00093 *
          naxis
                    int
                                 The number of world coordinate axes, used to determine
00094 *
                                 array sizes.
00095 *
00096 * Given and returned:
00097 *
          lin
                      struct linprm*
00098 *
                                 Linear transformation parameters. Note that, in order
00099 *
                                 to initialize memory management linprm::flag should be
00100 *
                                 set to -1 when lin is initialized for the first time
                                 (memory leaks may result if it had already been
00101 *
00102 *
                                 initialized).
00103 *
00104 * Given:
00105 *
                     int
                                 The number of DPja or DQia keywords to allocate space
          ndpmax
                                 for. If set to -1, the value of the global variable
00106 *
                                 NDPMAX will be used. This is potentially
00107 *
00108 *
                                 thread-unsafe if disndp() is being used dynamically to
00109 *
                                 alter its value.
00110 *
00111 * Function return value:
00112 *
                                 Status return value:
                     int
00113 *
                                   0: Success.
00114 *
                                   1: Null linprm pointer passed.
00115 *
                                   2: Memory allocation failed.
00116 *
00117 *
                                 For returns > 1. a detailed error message is set in
                                 linprm::err if enabled, see wcserr_enable().
00118 *
00120 *
00121 * lindis() - Assign a distortion to a linprm struct
00122 * -
00123 \star lindis() is a thin wrapper on lindist(). It invokes it with ndpmax set
00124 * to -1 which causes the value of the global variable NDPMAX to be used (by
```

```
00125 \star disinit()). It is thereby potentially thread-unsafe if NDPMAX is altered
00126 \star dynamically via disndp(). Use lindist() for a thread-safe alternative in
00127 * this case.
00128 *
00129 *
00130 * lindist() - Assign a distortion to a linprm struct
00131 *
00132 \star lindist() may be used to assign the address of a disprm struct to
00133 \star linprm::dispre or linprm::disseq. The linprm struct must already have been
00134 \star initialized by lininit().
00135 *
00136 \star The disprm struct must have been allocated from the heap (e.g. using
00137 * malloc(), calloc(), etc.). lindist() will immediately initialize it via a 00138 * call to disini() using the value of linprm::naxis. Subsequently, it will be
00139 \star reinitialized by calls to lininit(), and freed by linfree(), neither of
00140 \star which would happen if the disprm struct was assigned directly.
00141 *
00142 \star If the disprm struct had previously been assigned via lindist(), it will be
00143 * freed before reassignment. It is also permissable for a null disprm pointer
00144 \star to be assigned to disable the distortion correction.
00145 *
00146 * Given:
00147 *
          sequence int
                              Is it a prior or sequent distortion?
00148 *
                                   1: Prior, the assignment is to linprm::dispre.
00149 *
                                   2: Sequent, the assignment is to linprm::disseq.
00150 *
00151 *
                                Anything else is an error.
00152 *
00153 * Given and returned:
00154 *
          lin
                    struct linprm*
00155 *
                                Linear transformation parameters.
00156 *
00157 *
          dis
                     struct disprm*
00158 *
                                Distortion function parameters.
00159 *
00160 * Given:
00161 *
                                The number of DPja or DQia keywords to allocate space
          ndpmax
                    int
                                 for. If set to -1, the value of the global variable
00162 *
00163 *
                                NDPMAX will be used. This is potentially
00164 *
                                thread-unsafe if disndp() is being used dynamically to
00165 *
                                alter its value.
00166 *
00167 * Function return value:
00168 *
                                Status return value:
                     int
                                   0: Success.
00169 *
00170 *
                                   1: Null linprm pointer passed.
00171 *
                                   4: Invalid sequence.
00172 *
00173 *
00174 * lincpy() - Copy routine for the linprm struct
00176 \star lincpy() does a deep copy of one linprm struct to another, using lininit() 00177 \star to allocate memory for its arrays if required. Only the "information to be
00178 \star provided" part of the struct is copied; a call to linset() is required to
00179 * initialize the remainder.
00180 *
00181 * Given:
00182 *
          alloc
                                If true, allocate memory for the crpix, pc, and cdelt
00183 *
                                 arrays in the destination. Otherwise, it is assumed
00184 *
                                that pointers to these arrays have been set by the
                                user except if they are null pointers in which case
00185 *
00186 *
                                memory will be allocated for them regardless.
00187 *
00188 *
          linsrc
                   const struct linprm*
00189 *
                                Struct to copy from.
00190 *
00191 * Given and returned:
00192 *
                    struct linprm*
          lindst
                                Struct to copy to. linprm::flag should be set to -1
00193 *
00194 *
                                if lindst was not previously initialized (memory leaks
00195 *
                                may result if it was previously initialized).
00196 *
00197 * Function return value:
                                Status return value:
00198 *
                     int
00199 *
                                  0: Success.
00200 *
                                   1: Null linprm pointer passed.
00201 *
                                   2: Memory allocation failed.
00202 *
00203 *
                                For returns > 1, a detailed error message is set in
                                linprm::err if enabled, see wcserr_enable().
00204 *
00205 *
00207 * linfree() - Destructor for the linprm struct
00208 * -
00209 \star linfree() frees memory allocated for the linprm arrays by lininit() and/or
00210 \star linset(). lininit() keeps a record of the memory it allocates and linfree() 00211 \star will only attempt to free this.
```

```
00213 \star PLEASE NOTE: linfree() must not be invoked on a linprm struct that was not
00214 * initialized by lininit().
00215 *
00216 * Given:
00217 *
                    struct linprm*
          lin
00218 *
                               Linear transformation parameters.
00219 *
00220 * Function return value:
00221 *
                    int
                               Status return value:
00222 *
                                 0: Success.
00223 *
                                 1: Null linprm pointer passed.
00224 *
00225 *
00226 \star linsize() - Compute the size of a linprm struct
00227 *
00228 * linsize() computes the full size of a linprm struct, including allocated
00229 * memory.
00230 *
00231 * Given:
                   const struct linprm*
00232 * lin
00233 *
                               Linear transformation parameters.
00234 *
00235 *
                               If NULL, the base size of the struct and the allocated
00236 *
                               size are both set to zero.
00237 *
00238 * Returned:
00239 *
                    int[2]
                             The first element is the base size of the struct as
         sizes
00240 *
                               returned by sizeof(struct linprm).
00241 *
00242 *
                               The second element is the total size of memory
                               allocated in the struct, in bytes, assuming that the allocation was done by lininit(). This figure
00243 *
00244 *
00245 *
                               includes memory allocated for members of constituent
00246 *
                                                                  such as linprm::dispre.
                               structs, *
00247 *
00248 *
                               It is not an error for the struct not to have been set
                               up via linset(), which normally results in additional
00250 *
                               memory allocation.
00251 *
00252 * Function return value:
00253 *
                               Status return value:
                    int.
00254 *
                                 0: Success.
00255 *
00256 *
00257 \star lineng() - enquire about the state of a linprm struct
00258 *
00259 \star linenq() may be used to obtain information about the state of a linprm
00260 \star struct. The function returns a true/false answer for the enquiry asked.
00261 *
00262 * Given:
00263 * lin
                   const struct linprm*
00264 *
                               Linear transformation parameters.
00265 *
00266 *
          enquiry int
                               Enquiry according to the following parameters:
00267 *
                                 LINENQ_MEM: memory in the struct is being managed by
                                             WCSLIB (see lininit()).
00268 *
00269 *
                                 LINENQ_SET: the struct has been set up by linset().
00270 *
                                 LINENQ_BYP: the struct is in bypass mode (see
00271 *
                                              linset()).
00272 *
                               These may be combined by logical OR, e.g.
00273 *
                               LINENQ_MEM | LINENQ_SET. The enquiry result will be
00274 *
                               the logical AND of the individual results.
00275 *
00276 * Function return value:
00277 *
                               Enquiry result:
                    int
00278 *
                                 0: No.
00279 *
                                 1: Yes.
00280 *
00282 * linprt() - Print routine for the linprm struct
00283 *
00284 \star linprt() prints the contents of a linprm struct using wcsprintf(). Mainly 00285 \star intended for diagnostic purposes.
00286 *
00287 * Given:
00288 *
                    const struct linprm*
00289 *
                               Linear transformation parameters.
00290 *
00291 * Function return value:
00292 *
                             Status return value:
                   int
00293 *
                                 0: Success.
00294 *
                                 1: Null linprm pointer passed.
00295 *
00296
00297 * linperr() - Print error messages from a linprm struct
00298 *
```

```
00299 \star linperr() prints the error message(s) (if any) stored in a linprm struct,
00300 \star and the disprm structs that it may contain. If there are no errors then
00301 * nothing is printed. It uses wcserr_prt(), q.v.
00302 *
00303 * Given:
00304 *
                    const struct linprm*
          lin
                                 Coordinate transformation parameters.
00306 *
00307 *
          prefix
                    const char *
                                 If non-NULL, each output line will be prefixed with
00308 *
00309 *
                                 this string.
00310 *
00311 * Function return value:
00312 *
                                 Status return value:
00313 *
                                   0: Success.
00314 *
                                   1: Null linprm pointer passed.
00315 *
00316 *
00317 * linset() - Setup routine for the linprm struct
00319 \star linset(), if necessary, allocates memory for the linprm::piximg and
00320 \star linprm::imgpix arrays and sets up the linprm struct according to information
00321 * supplied within it - refer to the explanation of linprm::flag.
00322 *
00323 \star Note that this routine need not be called directly; it will be invoked by
00324 * linp2x() and linx2p() if the linprm::flag is anything other than a
00325 * predefined magic value.
00326 *
00327 \star linset() normally operates regardless of the value of linprm::flag; i.e.
00328 * even if a struct was previously set up it will be reset unconditionally.
00329 * However, a linprm struct may be put into "bypass" mode by invoking linset()
00330 * initially with linprm::flag == 1 (rather than 0). linset() will return
00331 * immediately if invoked on a struct in that state. To take a struct out of
00332 \star bypass mode, simply reset linprm::flag to zero. See also lineng().
00333 *
00334 * Given and returned:
00335 * lin struct linprm*
                                 Linear transformation parameters.
00337 *
00338 * Function return value:
00339 *
                      int
                                 Status return value:
00340 *
                                   0: Success.
00341 *
                                   1: Null linprm pointer passed.
00342 *
                                   2: Memory allocation failed.
                                    3: PCi_ja matrix is singular.
00343 *
00344 *
                                   4: Failed to initialise distortions.
00345 *
00346 *
                                 For returns > 1, a detailed error message is set in
                                 linprm::err if enabled, see wcserr_enable().
00347 *
00348
00350 * linp2x() - Pixel-to-world linear transformation
00351 *
00352 \star linp2x() transforms pixel coordinates to intermediate world coordinates.
00353 *
00354 * Given and returned:
00355 * lin
                     struct linprm*
00356 *
                                 Linear transformation parameters.
00357 *
00358 * Given:
00359 *
          ncoord.
00360 *
                                 The number of coordinates, each of vector length nelem
          nelem
                     int
00361 *
                                 but containing lin.naxis coordinate elements.
00362 *
00363 * pixcrd
                     const double[ncoord][nelem]
00364 *
                                 Array of pixel coordinates.
00365 *
00366 * Returned:
00367 * imgcrd
                      double[ncoord][nelem]
00368 *
                                 Array of intermediate world coordinates.
00369 *
00370 * Function return value:
00371 *
                      int
                                 Status return value:
00372 *
                                   0: Success.
00373 *
                                   1: Null linprm pointer passed.
00374 *
                                    2: Memory allocation failed.
00375 *
                                   3: PCi_ja matrix is singular.
00376 *
                                   4: Failed to initialise distortions.
00377 *
                                   5: Distort error.
00378 *
00379 *
                                 For returns > 1, a detailed error message is set in
00380 *
                                 linprm::err if enabled, see wcserr_enable().
00381 *
00382 * Notes:
00383 \star 1. Historically, the API to linp2x() did not have a stat[] vector because
00384 *
              a valid linear transformation should always succeed. However, now that
00385 *
              it invokes \operatorname{disp2x}() if distortions are present, it does have the
```

```
potential to fail. Consequently, when distortions are present and a
              status return (stat[]) is required for each coordinate, then linp2x()
00388 *
              should be invoked separately for each of them.
00389 *
00390 *
00391 * linx2p() - World-to-pixel linear transformation
00393 \star linx2p() transforms intermediate world coordinates to pixel coordinates.
00394 *
00395 \star Given and returned:
                     struct linprm*
00396 *
          lin
00397 *
                                Linear transformation parameters.
00398 *
00399 * Given:
00400 *
         ncoord,
00401 *
          nelem
                                The number of coordinates, each of vector length nelem
00402 *
                                but containing lin.naxis coordinate elements.
00403 *
00404 *
         imgcrd const double[ncoord][nelem]
00405 *
                                Array of intermediate world coordinates.
00406 *
00407 * Returned:
00408 *
         pixcrd
                     double[ncoord][nelem]
                                Array of pixel coordinates.
00409 *
00410 *
00411 *
                                Status return value:
00412 *
00413 *
                                  1: Null linprm pointer passed.
00414 *
                                  2: Memory allocation failed.
00415 *
                                  3: PCi_ja matrix is singular.
00416 *
                                  4: Failed to initialise distortions.
00417 *
                                  6: De-distort error.
00418 *
00419 *
                                For returns > 1, a detailed error message is set in
00420 *
                                linprm::err if enabled, see wcserr_enable().
00421 *
00422 * Notes:
         1. Historically, the API to linx2p() did not have a stat[] vector because
00424 *
             a valid linear transformation should always succeed. However, now that
             it invokes disx2p() if distortions are present, it does have the potential to fail. Consequently, when distortions are present and a
00425 *
00426 *
              status return (stat[]) is required for each coordinate, then linx2p()
00427 *
00428 *
              should be invoked separately for each of them.
00429 *
00430 *
00431 * linwarp() - Compute measures of distortion
00432 *
00433 \star linwarp() computes various measures of the distortion over a specified range
00434 * of pixel coordinates.
00435 *
00436 * All distortion measures are specified as an offset in pixel coordinates,
00437 \star as given directly by prior distortions. The offset in intermediate pixel
00438 \star coordinates given by sequent distortions is translated back to pixel
00439 \star coordinates by applying the inverse of the linear transformation matrix
00440 \star (PCi_ja or CDi_ja). The difference may be significant if the matrix
00441 * introduced a scaling.
00443 \star If all distortions are prior, then linwarp() uses diswarp(), q.v.
00444 *
00445 * Given and returned:
                    struct linprm*
00446 *
         lin
00447 *
                                Linear transformation parameters plus distortions.
00448 *
00449 * Given:
          pixblc
00450 *
                     const double[naxis]
                                Start of the range of pixel coordinates (i.e. "bottom left-hand corner" in the conventional FITS image
00451 *
00452 *
00453 *
                                display orientation). May be specified as a NULL
00454 *
                                pointer which is interpreted as (1,1,...).
00455 *
00456 *
          pixtrc
                     const double[naxis]
00457 *
                                End of the range of pixel coordinates (i.e. "top
                                right-hand corner" in the conventional FITS image
00458 *
00459 *
                                display orientation).
00460 *
00461 *
                   const double[naxis]
          pixsamp
00462 *
                                If positive or zero, the increment on the particular
                                axis, starting at pixblc[]. Zero is interpreted as a unit increment. pixsamp may also be specified as a NULL pointer which is interpreted as all zeroes, i.e.
00463 *
00464 *
00465 *
00466 *
                                unit increments on all axes.
00467
00468 *
                                If negative, the grid size on the particular axis (the
00469 *
                                absolute value being rounded to the nearest integer).
00470 *
                                For example, if pixsamp is (-128.0,-128.0,...) then
                                each axis will be sampled at 128 points between
00471 *
                                pixblc[] and pixtrc[] inclusive. Use caution when
00472 *
```

```
00473 *
                               using this option on non-square images.
00474 *
00475 * Returned:
00476 *
          nsamp
                    int.*
                               The number of pixel coordinates sampled.
00477 *
00478 *
                               Can be specified as a NULL pointer if not required.

00509 *
                               root mean square deviation of the distortion.
00510 *
00511 *
                               Can be specified as a NULL pointer if not required.
00512 *
00513 * Function return value:
00514 *
                    int
                               Status return value:
00515 *
                                 0: Success.
00516 *
                                 1: Null linprm pointer passed.
00517 *
                                 2: Memory allocation failed.
                                 3: Invalid parameter.
00518
00519 *
                                 4: Distort error.
00520 *
00521 *
00522 * linprm struct - Linear transformation parameters
00524 \star The linprm struct contains all of the information required to perform a
00525 \star linear transformation. It consists of certain members that must be set by
00526 \star the user ("given") and others that are set by the WCSLIB routines
00527 * ("returned").
00528 *
00529 *
          int flag
00530 *
            (Given and returned) This flag must be set to zero (or 1, see linset())
00531 *
            whenever any of the following linprm members are set or changed:
00532 *
00533 *
              - linprm::naxis (q.v., not normally set by the user),
00534 *
             - linprm::pc,
00535 *
              - linprm::cdelt,
00536 *
              - linprm::dispre.
00537 *
              - linprm::disseq.
00538 *
            This signals the initialization routine, linset(), to recompute the returned members of the linprm struct. linset() will reset flag to
00539 *
00540 *
00541 *
            indicate that this has been done.
00542 *
00543 *
            PLEASE NOTE: flag should be set to -1 when liminit() is called for the
00544 *
            first time for a particular linprm struct in order to initialize memory
00545 *
            management. It must ONLY be used on the first initialization otherwise
00546 *
            memory leaks may result.
00547 *
00548 *
00549 *
            (Given or returned) Number of pixel and world coordinate elements.
00550 *
00551 *
            If lininit() is used to initialize the linprm struct (as would normally
            be the case) then it will set naxis from the value passed to it as a
00552 *
00553 *
            function argument. The user should not subsequently modify it.
00554
00555 *
00556 *
            (Given) Pointer to the first element of an array of double containing
00557 *
            the coordinate reference pixel, CRPIXja.
00558 *
00559 *
            It is not necessary to reset the linprm struct (via linset()) when
```

```
00560 *
            linprm::crpix is changed.
00561 *
00562 *
             (Given) Pointer to the first element of the PCi_ja (pixel coordinate)
00563 *
00564 *
            transformation matrix. The expected order is
00565 *
00566 =
               struct linprm lin;
00567 =
               lin.pc = {PC1_1, PC1_2, PC2_1, PC2_2};
00568 *
00569 *
            This may be constructed conveniently from a 2-D array via
00570 *
              double m[2][2] = \{ \{PC1_1, PC1_2\}, \}
00571 =
00572 =
                                  {PC2 1, PC2 2}};
00573 *
00574 *
            which is equivalent to
00575 *
00576 =
              double m[2][2];
00577 =
              m[0][0] = PC1_1;
m[0][1] = PC1_2;
00578 =
00579 =
              m[1][0] = PC2_1;
00580 =
              m[1][1] = PC2_2;
00581 *
00582 *
            The storage order for this 2-D array is the same as for the 1-D array,
00583 *
            whence
00584 *
00585 =
              lin.pc = *m;
00586 *
00587 *
            would be legitimate.
00588 *
00589 *
          double *cdelt
00590 *
            (Given) Pointer to the first element of an array of double containing
00591 *
            the coordinate increments, CDELTia.
00592 *
00593 *
          struct disprm *dispre
00594 *
             (Given) Pointer to a disprm struct holding parameters for prior {\bf r}
00595 *
            distortion functions, or a null (0x0) pointer if there are none.
00596 *
00597 *
            Function lindist() may be used to assign a disprm pointer to a linprm
00598 *
             struct, allowing it to take control of any memory allocated for it, as
00599 *
             in the following example:
00600 *
00601 =
              void add_distortion(struct linprm *lin)
00602 =
00603 =
                struct disprm *dispre;
00604 =
00605 =
                 dispre = malloc(sizeof(struct disprm));
00606 =
                 dispre->flag = -1;
00607 =
                lindist(1, lin, dispre, ndpmax);
00608 =
00609 =
                  (Set up dispre.)
00610 =
                   :
00611 =
00612 =
                 return;
00613 =
00614 *
00615 *
            Here, after the distortion function parameters etc. are copied into
            dispre, dispre is assigned using lindist() which takes control of the
00617 *
             allocated memory. It will be freed later when linfree() is invoked on
00618 *
            the linprm struct.
00619 *
00620 *
            Consider also the following erroneous code:
00621 *
00622 =
              void bad_code(struct linprm *lin)
00623 =
00624 =
                 struct disprm dispre;
00625 =
                dispre.flag = -1;
lindist(1, lin, &dispre, ndpmax);  // WRONG.
00626 =

00630 =
00631 =
00632 *
00633 *
            Here, dispre is declared as a struct, rather than a pointer. When the
            function returns, dispre will go out of scope and its memory will most likely be reused, thereby trashing its contents. Later, a segfault will
00634 *
00635 *
00636 *
            occur when linfree() tries to free dispre's stale address.
00637 *
00638 *
          struct disprm *disseq
00639 *
             (Given) Pointer to a disprm struct holding parameters for sequent
00640 *
            distortion functions, or a null (0x0) pointer if there are none.
00641 *
00642 *
            Refer to the comments and examples given for disprm::dispre.
00643 *
          double *piximg
00644 *
            (Returned) Pointer to the first element of the matrix containing the
00645 *
00646 *
            product of the CDELTia diagonal matrix and the PCi ja matrix.
```

```
00647 *
00648 *
           double *imapix
           (Returned) Pointer to the first element of the inverse of the
00649 *
00650 *
            linprm::piximg matrix.
00651 *
00652 *
          int i naxis
            (Returned) The dimension of linprm::piximg and linprm::imgpix (normally
00654 *
             equal to naxis).
00655 *
00656 *
          int unity
            (Returned) True if the linear transformation matrix is unity.
00657 *
00658 *
00659 *
          int affine
00660 *
            (Returned) True if there are no distortions.
00661 *
00662 *
          int simple
00663 *
           (Returned) True if unity and no distortions.
00664 *
00665 *
          struct wcserr *err
           (Returned) If enabled, when an error status is returned, this struct contains detailed information about the error, see wcserr_enable().

Functions

- int logx2s (double crval, int nx, int sx, int slogc, const double x[], double logc[], int stat[])

 Transform to logarithmic coordinates.
- int logs2x (double crval, int nlogc, int slogc, int sx, const double logc[], double x[], int stat[])

 *Transform logarithmic coordinates.

Variables

const char * log_errmsg []
 Status return messages.

6.11.1 Detailed Description

Routines in this suite implement the part of the FITS World Coordinate System (WCS) standard that deals with logarithmic coordinates, as described in

"Representations of world coordinates in FITS", Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061 (WCS Paper I)

"Representations of spectral coordinates in FITS", Greisen, E.W., Calabretta, M.R., Valdes, F.G., & Allen, S.L. 2006, A&A, 446, 747 (WCS Paper III)

These routines define methods to be used for computing logarithmic world coordinates from intermediate world coordinates (a linear transformation of image pixel coordinates), and vice versa.

logx2s() and logs2x() implement the WCS logarithmic coordinate transformations.

Argument checking:

The input log-coordinate values are only checked for values that would result in floating point exceptions and the same is true for the log-coordinate reference value.

Accuracy:

No warranty is given for the accuracy of these routines (refer to the copyright notice); intending users must satisfy for themselves their adequacy for the intended purpose. However, closure effectively to within double precision rounding error was demonstrated by test routine tlog.c which accompanies this software.

6.11.3 Function Documentation

logx2s()

Transform to logarithmic coordinates.

logx2s() transforms intermediate world coordinates to logarithmic coordinates.

Parameters

in,out	crval	Log-coordinate reference value (CRVALia).	
in	nx	Vector length.	
in	SX	Vector stride.	
in	slogc	Vector stride.	
in	X	Intermediate world coordinates, in SI units.	
out	logc	Logarithmic coordinates, in SI units.	
out	stat	Status return value status for each vector element: • 0: Success.	

Returns

Status return value:

- 0: Success.
- 2: Invalid log-coordinate reference value.

logs2x()

Transform logarithmic coordinates.

logs2x() transforms logarithmic world coordinates to intermediate world coordinates.

6.12 log.h 179

Parameters

in,out	crval	Log-coordinate reference value (CRVALia).	
in	nlogc	Vector length.	
in	slogc	Vector stride.	
in	SX	Vector stride.	
in	logc	Logarithmic coordinates, in SI units.	
out	x	Intermediate world coordinates, in SI units.	
out	stat	Status return value status for each vector element: • 0: Success.	
		1: Invalid value of logc.	

Returns

Status return value:

- 0: Success.
- · 2: Invalid log-coordinate reference value.
- · 4: One or more of the world-coordinate values are incorrect, as indicated by the stat vector.

6.11.4 Variable Documentation

log_errmsg

```
const char * log_errmsg[] [extern]
```

Status return messages.

Error messages to match the status value returned from each function.

6.12 log.h

00100 * Given and returned:
00101 *
         crval
                    double
                              Log-coordinate reference value (CRVALia).
00102 *
00103 * Given:
00104 *
                   int
         nlogc
                              Vector length.
00105 *
                              Vector stride.
00106 *
                   int
         slogc
00107 *
00108 *
          sx
                    int
                              Vector stride.
00109 *
00110 *
          logc
                    const double[]
00111 *
                               Logarithmic coordinates, in SI units.
```

```
00112 *
00113 * Returned:
00114 *
                    double[] Intermediate world coordinates, in SI units.
00115 *
00116 *
         stat
                   int[]
                            Status return value status for each vector element:
00117 *
                                0: Success.
                                1: Invalid value of logc.
00118 *
00119 *
00120 * Function return value:
00121 *
                    int
                              Status return value:
00122 *
                                 0: Success.
00123 *
                                 2: Invalid log-coordinate reference value.
00124 *
                                 4: One or more of the world-coordinate values
00125 *
                                    are incorrect, as indicated by the stat vector.
00126 *
00127 *
00128 * Global variable: const char *log_errmsg[] - Status return messages
00129 *
00130 \star Error messages to match the status value returned from each function.

```

Functions

• int prjini (struct prjprm *prj)

Default constructor for the prjprm struct.

int prjfree (struct prjprm *prj)

Destructor for the priprm struct.

• int prjsize (const struct prjprm *prj, int sizes[2])

Compute the size of a prjprm struct.

int prjenq (const struct prjprm *prj, int enquiry)

enquire about the state of a priprm struct.

• int priprt (const struct priprm *prj)

Print routine for the prjprm struct.

int prjperr (const struct prjprm *prj, const char *prefix)

Print error messages from a priprm struct.

int prjbchk (double tol, int nphi, int ntheta, int spt, double phi[], double theta[], int stat[])

Bounds checking on native coordinates.

int prjset (struct prjprm *prj)

Generic setup routine for the prjprm struct.

• int prjx2s (PRJX2S_ARGS)

Generic Cartesian-to-spherical deprojection.

• int prjs2x (PRJS2X_ARGS)

Generic spherical-to-Cartesian projection.

int azpset (struct prjprm *prj)

Set up a priprm struct for the zenithal/azimuthal perspective (AZP) projection.

int azpx2s (PRJX2S_ARGS)

Cartesian-to-spherical transformation for the zenithal/azimuthal perspective (AZP) projection.

int azps2x (PRJS2X_ARGS)

Spherical-to-Cartesian transformation for the zenithal/azimuthal perspective (AZP) projection.

int szpset (struct prjprm *prj)

Set up a prjprm struct for the slant zenithal perspective (SZP) projection.

• int szpx2s (PRJX2S_ARGS)

Cartesian-to-spherical transformation for the slant zenithal perspective (SZP) projection.

int szps2x (PRJS2X_ARGS)

Spherical-to-Cartesian transformation for the slant zenithal perspective (SZP) projection.

int tanset (struct prjprm *prj)

Set up a prjprm struct for the gnomonic (TAN) projection.

int tanx2s (PRJX2S ARGS)

Cartesian-to-spherical transformation for the gnomonic (TAN) projection.

int tans2x (PRJS2X ARGS)

Spherical-to-Cartesian transformation for the gnomonic (TAN) projection.

int stgset (struct prjprm *prj)

Set up a priprm struct for the stereographic (STG) projection.

• int stgx2s (PRJX2S_ARGS)

Cartesian-to-spherical transformation for the stereographic (STG) projection.

int stgs2x (PRJS2X_ARGS)

Spherical-to-Cartesian transformation for the stereographic (STG) projection.

int sinset (struct priprm *prj)

Set up a priprm struct for the orthographic/synthesis (SIN) projection.

int sinx2s (PRJX2S ARGS)

Cartesian-to-spherical transformation for the orthographic/synthesis (SIN) projection.

int sins2x (PRJS2X ARGS)

Spherical-to-Cartesian transformation for the orthographic/synthesis (SIN) projection.

• int arcset (struct prjprm *prj)

Set up a priprm struct for the zenithal/azimuthal equidistant (ARC) projection.

int arcx2s (PRJX2S_ARGS)

Cartesian-to-spherical transformation for the zenithal/azimuthal equidistant (ARC) projection.

• int arcs2x (PRJS2X ARGS)

Spherical-to-Cartesian transformation for the zenithal/azimuthal equidistant (ARC) projection.

• int zpnset (struct prjprm *prj)

Set up a prjprm struct for the zenithal/azimuthal polynomial (ZPN) projection.

int zpnx2s (PRJX2S ARGS)

Cartesian-to-spherical transformation for the zenithal/azimuthal polynomial (ZPN) projection.

int zpns2x (PRJS2X_ARGS)

Spherical-to-Cartesian transformation for the zenithal/azimuthal polynomial (ZPN) projection.

int zeaset (struct prjprm *prj)

Set up a priprm struct for the zenithal/azimuthal equal area (ZEA) projection.

• int zeax2s (PRJX2S_ARGS)

Cartesian-to-spherical transformation for the zenithal/azimuthal equal area (ZEA) projection.

int zeas2x (PRJS2X_ARGS)

Spherical-to-Cartesian transformation for the zenithal/azimuthal equal area (ZEA) projection.

• int airset (struct prjprm *prj)

Set up a priprm struct for Airy's (AIR) projection.

• int airx2s (PRJX2S ARGS)

Cartesian-to-spherical transformation for Airy's (AIR) projection.

int airs2x (PRJS2X_ARGS)

Spherical-to-Cartesian transformation for Airy's (AIR) projection.

• int cypset (struct prjprm *prj)

Set up a priprm struct for the cylindrical perspective (CYP) projection.

int cypx2s (PRJX2S_ARGS)

Cartesian-to-spherical transformation for the cylindrical perspective (CYP) projection.

int cyps2x (PRJS2X_ARGS)

Spherical-to-Cartesian transformation for the cylindrical perspective (CYP) projection.

int ceaset (struct prjprm *prj)

Set up a priprm struct for the cylindrical equal area (CEA) projection.

• int ceax2s (PRJX2S_ARGS)

Cartesian-to-spherical transformation for the cylindrical equal area (CEA) projection.

int ceas2x (PRJS2X ARGS)

Spherical-to-Cartesian transformation for the cylindrical equal area (CEA) projection.

int carset (struct prjprm *prj)

Set up a priprm struct for the plate carrée (CAR) projection.

int carx2s (PRJX2S ARGS)

Cartesian-to-spherical transformation for the plate carrée (CAR) projection.

int cars2x (PRJS2X ARGS)

Spherical-to-Cartesian transformation for the plate carrée (CAR) projection.

int merset (struct prjprm *prj)

Set up a priprm struct for Mercator's (MER) projection.

int merx2s (PRJX2S ARGS)

Cartesian-to-spherical transformation for Mercator's (MER) projection.

int mers2x (PRJS2X_ARGS)

Spherical-to-Cartesian transformation for Mercator's (MER) projection.

int sflset (struct prjprm *prj)

Set up a priprm struct for the Sanson-Flamsteed (SFL) projection.

int sflx2s (PRJX2S_ARGS)

Cartesian-to-spherical transformation for the Sanson-Flamsteed (SFL) projection.

int sfls2x (PRJS2X ARGS)

Spherical-to-Cartesian transformation for the Sanson-Flamsteed (SFL) projection.

• int parset (struct prjprm *prj)

Set up a priprm struct for the parabolic (PAR) projection.

int parx2s (PRJX2S_ARGS)

Cartesian-to-spherical transformation for the parabolic (PAR) projection.

• int pars2x (PRJS2X_ARGS)

Spherical-to-Cartesian transformation for the parabolic (PAR) projection.

• int molset (struct prjprm *prj)

Set up a priprm struct for Mollweide's (MOL) projection.

int molx2s (PRJX2S_ARGS)

Cartesian-to-spherical transformation for Mollweide's (MOL) projection.

• int mols2x (PRJS2X ARGS)

Spherical-to-Cartesian transformation for Mollweide's (MOL) projection.

int aitset (struct prjprm *prj)

Set up a priprm struct for the Hammer-Aitoff (AIT) projection.

• int aitx2s (PRJX2S ARGS)

Cartesian-to-spherical transformation for the Hammer-Aitoff (AIT) projection.

int aits2x (PRJS2X_ARGS)

Spherical-to-Cartesian transformation for the Hammer-Aitoff (AIT) projection.

int copset (struct prjprm *prj)

Set up a prjprm struct for the conic perspective (COP) projection.

• int copx2s (PRJX2S ARGS)

Cartesian-to-spherical transformation for the conic perspective (COP) projection.

int cops2x (PRJS2X_ARGS)

Spherical-to-Cartesian transformation for the conic perspective (COP) projection.

int coeset (struct priprm *prj)

Set up a prjprm struct for the conic equal area (COE) projection.

• int coex2s (PRJX2S ARGS)

Cartesian-to-spherical transformation for the conic equal area (COE) projection.

int coes2x (PRJS2X ARGS)

Spherical-to-Cartesian transformation for the conic equal area (COE) projection.

int codset (struct prjprm *prj)

Set up a priprm struct for the conic equidistant (COD) projection.

int codx2s (PRJX2S ARGS)

Cartesian-to-spherical transformation for the conic equidistant (COD) projection.

int cods2x (PRJS2X ARGS)

Spherical-to-Cartesian transformation for the conic equidistant (COD) projection.

int cooset (struct prjprm *prj)

Set up a priprm struct for the conic orthomorphic (COO) projection.

• int coox2s (PRJX2S ARGS)

Cartesian-to-spherical transformation for the conic orthomorphic (COO) projection.

int coos2x (PRJS2X_ARGS)

Spherical-to-Cartesian transformation for the conic orthomorphic (COO) projection.

int bonset (struct prjprm *prj)

Set up a priprm struct for Bonne's (BON) projection.

int bonx2s (PRJX2S_ARGS)

Cartesian-to-spherical transformation for Bonne's (BON) projection.

• int bons2x (PRJS2X ARGS)

Spherical-to-Cartesian transformation for Bonne's (BON) projection.

int pcoset (struct prjprm *prj)

Set up a prjprm struct for the polyconic (PCO) projection.

int pcox2s (PRJX2S_ARGS)

Cartesian-to-spherical transformation for the polyconic (PCO) projection.

• int pcos2x (PRJS2X ARGS)

Spherical-to-Cartesian transformation for the polyconic (PCO) projection.

int tscset (struct prjprm *prj)

Set up a priprm struct for the tangential spherical cube (TSC) projection.

int tscx2s (PRJX2S_ARGS)

Cartesian-to-spherical transformation for the tangential spherical cube (TSC) projection.

int tscs2x (PRJS2X_ARGS)

Spherical-to-Cartesian transformation for the tangential spherical cube (TSC) projection.

int cscset (struct prjprm *prj)

Set up a prjprm struct for the COBE spherical cube (CSC) projection.

int cscx2s (PRJX2S_ARGS)

Cartesian-to-spherical transformation for the COBE spherical cube (CSC) projection.

• int cscs2x (PRJS2X_ARGS)

Spherical-to-Cartesian transformation for the COBE spherical cube (CSC) projection.

• int qscset (struct prjprm *prj)

Set up a priprm struct for the quadrilateralized spherical cube (QSC) projection.

int qscx2s (PRJX2S_ARGS)

Cartesian-to-spherical transformation for the quadrilateralized spherical cube (QSC) projection.

• int qscs2x (PRJS2X_ARGS)

Spherical-to-Cartesian transformation for the quadrilateralized spherical cube (QSC) projection.

int hpxset (struct prjprm *prj)

Set up a priprm struct for the HEALPix (HPX) projection.

• int hpxx2s (PRJX2S_ARGS)

Cartesian-to-spherical transformation for the HEALPix (HPX) projection.

• int hpxs2x (PRJS2X ARGS)

Spherical-to-Cartesian transformation for the HEALPix (HPX) projection.

- int xphset (struct priprm *pri)
- int xphx2s (PRJX2S_ARGS)
- int xphs2x (PRJS2X_ARGS)

Variables

const char * prj_errmsg []

Status return messages.

const int CONIC

Identifier for conic projections.

· const int CONVENTIONAL

Identifier for conventional projections.

· const int CYLINDRICAL

Identifier for cylindrical projections.

· const int POLYCONIC

Identifier for polyconic projections.

const int PSEUDOCYLINDRICAL

Identifier for pseudocylindrical projections.

const int QUADCUBE

Identifier for quadcube projections.

· const int ZENITHAL

Identifier for zenithal/azimuthal projections.

const int HEALPIX

Identifier for the HEALPix projection.

• const char prj_categories [9][32]

Projection categories.

· const int prj_ncode

The number of recognized three-letter projection codes.

· const char prj_codes [28][4]

Recognized three-letter projection codes.

6.13.1 Detailed Description

Routines in this suite implement the spherical map projections defined by the FITS World Coordinate System (WCS) standard, as described in

```
"Representations of world coordinates in FITS",
Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061 (WCS Paper I)

"Representations of celestial coordinates in FITS",
Calabretta, M.R., & Greisen, E.W. 2002, A&A, 395, 1077 (WCS Paper II)

"Mapping on the HEALPix grid",
Calabretta, M.R., & Roukema, B.F. 2007, MNRAS, 381, 865 (WCS Paper V)

"Representing the 'Butterfly' Projection in FITS -- Projection Code XPH",
Calabretta, M.R., & Lowe, S.R. 2013, PASA, 30, e050 (WCS Paper VI)
```

These routines are based on the prjprm struct which contains all information needed for the computations. The struct contains some members that must be set by the user, and others that are maintained by these routines, somewhat like a C++ class but with no encapsulation.

Routine prjini() is provided to initialize the prjprm struct with default values, prjfree() reclaims any memory that may have been allocated to store an error message, prjsize() computes its total size including allocated memory, prjenq() returns information about the state of the struct, and prjprt() prints its contents.

prjperr() prints the error message(s) (if any) stored in a prjprm struct. prjbchk() performs bounds checking on native spherical coordinates.

Setup routines for each projection with names of the form ???set(), where "???" is the down-cased three-letter projection code, compute intermediate values in the prjprm struct from parameters in it that were supplied by the

user. The struct always needs to be set by the projection's setup routine but that need not be called explicitly - refer to the explanation of prjprm::flag.

Each map projection is implemented via separate functions for the spherical projection, ???s2x(), and deprojection, ???x2s().

A set of driver routines, prjset(), prjx2s(), and prjs2x(), provides a generic interface to the specific projection routines which they invoke via pointers-to-functions stored in the prjprm struct.

In summary, the routines are:

- prjini() Initialization routine for the prjprm struct.
- prjfree() Reclaim memory allocated for error messages.
- prjsize() Compute total size of a prjprm struct.
- prjprt() Print a prjprm struct.
- prjperr() Print error message (if any).
- prjbchk() Bounds checking on native coordinates.
- prjset(), prjx2s(), prjs2x(): Generic driver routines
- azpset(), azpx2s(), azps2x(): AZP (zenithal/azimuthal perspective)
- szpset(), szps2s(), szps2x(): SZP (slant zenithal perspective)
- tanset(), tanx2s(), tans2x(): TAN (gnomonic)
- stgset(), stgx2s(), stgs2x(): STG (stereographic)
- sinset(), sinx2s(), sins2x(): SIN (orthographic/synthesis)
- arcset(), arcx2s(), arcs2x(): ARC (zenithal/azimuthal equidistant)
- zpnset(), zpnx2s(), zpns2x(): **ZPN** (zenithal/azimuthal polynomial)
- zeaset(), zeax2s(), zeas2x(): ZEA (zenithal/azimuthal equal area)
- airset(), airx2s(), airs2x(): AIR (Airy)
- cypset(), cypx2s(), cyps2x(): CYP (cylindrical perspective)
- ceaset(), ceax2s(), ceas2x(): CEA (cylindrical equal area)
- carset(), carx2s(), cars2x(): CAR (Plate carée)
- merset(), merx2s(), mers2x(): MER (Mercator)
- sflset(), sflx2s(), sfls2x(): SFL (Sanson-Flamsteed)
- parset(), parx2s(), pars2x(): PAR (parabolic)
- molset(), molx2s(), mols2x(): MOL (Mollweide)
- aitset(), aitx2s(), aits2x(): AIT (Hammer-Aitoff)
- copset(), copx2s(), cops2x(): COP (conic perspective)
- coeset(), coex2s(), coes2x(): COE (conic equal area)
- codset(), codx2s(), cods2x(): COD (conic equidistant)
- cooset(), coox2s(), coos2x(): COO (conic orthomorphic)

```
    bonset(), bonx2s(), bons2x(): BON (Bonne)
```

- pcoset(), pcox2s(), pcos2x(): PCO (polyconic)
- tscset(), tscx2s(), tscs2x(): TSC (tangential spherical cube)
- cscset(), cscx2s(), cscs2x(): CSC (COBE spherical cube)
- qscset(), qscx2s(), qscs2x(): QSC (quadrilateralized spherical cube)
- hpxset(), hpxx2s(), hpxs2x(): HPX (HEALPix)
- xphset(), xphx2s(), xphs2x(): XPH (HEALPix polar, aka "butterfly")

Argument checking (projection routines):

The values of ϕ and θ (the native longitude and latitude) normally lie in the range $[-180^\circ, 180^\circ]$ for ϕ , and $[-90^\circ, 90^\circ]$ for θ . However, all projection routines will accept any value of ϕ and will not normalize it.

The projection routines do not explicitly check that θ lies within the range $[-90^\circ, 90^\circ]$. They do check for any value of θ that produces an invalid argument to the projection equations (e.g. leading to division by zero). The projection routines for **AZP**, **SZP**, **TAN**, **SIN**, **ZPN**, and **COP** also return error 2 if (ϕ, θ) corresponds to the overlapped (far) side of the projection but also return the corresponding value of (x, y). This strict bounds checking may be relaxed at any time by setting priprm::bounds%2 to 0 (rather than 1); the projections need not be reinitialized.

Argument checking (deprojection routines):

Error checking on the projected coordinates (x,y) is limited to that required to ascertain whether a solution exists. Where a solution does exist, an optional check is made that the value of ϕ and θ obtained lie within the ranges $[-180^\circ, 180^\circ]$ for ϕ , and $[-90^\circ, 90^\circ]$ for θ . This check, performed by prjbchk(), is enabled by default. It may be disabled by setting prjprm::bounds%4 to 0 (rather than 1); the projections need not be reinitialized.

Accuracy:

No warranty is given for the accuracy of these routines (refer to the copyright notice); intending users must satisfy for themselves their adequacy for the intended purpose. However, closure to a precision of at least $0^{\circ}.0000000001$ of longitude and latitude has been verified for typical projection parameters on the 1° degree graticule of native longitude and latitude (to within 5° of any latitude where the projection may diverge). Refer to the tprj1.c and tprj2.c test routines that accompany this software.

6.13.2 Macro Definition Documentation

PVN

```
#define PVN 30
```

Total number of projection parameters.

The total number of projection parameters numbered 0 to PVN-1.

PRJX2S_ARGS

```
#define PRJX2S_ARGS
```

Value:

```
struct prjprm *prj, int nx, int ny, int sxy, int spt, \ const double x[], const double y[], double phi[], double theta[], int stat[]
```

For use in declaring deprojection function prototypes.

Preprocessor macro used for declaring deprojection function prototypes.

PRJS2X_ARGS

```
#define PRJS2X_ARGS
```

Value:

```
struct prjprm *prj, int nx, int ny, int sxy, int spt, \
const double phi[], const double theta[], double x[], double y[], int stat[]
```

For use in declaring projection function prototypes.

Preprocessor macro used for declaring projection function prototypes.

PRJLEN

```
#define PRJLEN (sizeof(struct prjprm)/sizeof(int))
```

Size of the priprm struct in int units.

Size of the prjprm struct in *int* units, used by the Fortran wrappers.

prjini_errmsg

```
#define prjini_errmsg prj_errmsg
```

Deprecated.

Deprecated Added for backwards compatibility, use prj_errmsg directly now instead.

prjprt_errmsg

```
#define prjprt_errmsg prj_errmsg
```

Deprecated.

Deprecated Added for backwards compatibility, use prj_errmsg directly now instead.

prjset_errmsg

```
#define prjset_errmsg prj_errmsg
```

Deprecated.

Deprecated Added for backwards compatibility, use prj_errmsg directly now instead.

prjx2s_errmsg

```
#define prjx2s_errmsg prj_errmsg
```

Deprecated.

Deprecated Added for backwards compatibility, use prj_errmsg directly now instead.

prjs2x_errmsg

```
#define prjs2x_errmsg prj_errmsg
```

Deprecated.

Deprecated Added for backwards compatibility, use prj_errmsg directly now instead.

6.13.3 Enumeration Type Documentation

prjenq_enum

```
enum prjenq_enum
```

Enumerator

```
PRJENQ_SET
PRJENQ BYP
```

prj_errmsg_enum

```
enum prj_errmsg_enum
```

6.13.4 Function Documentation

prjini()

```
int prjini ( {\tt struct\ prjprm\ *\ prj\ )}
```

Default constructor for the prjprm struct.

prjini() sets all members of a prjprm struct to default values. It should be used to initialize every prjprm struct.

PLEASE NOTE: If the prjprm struct has already been initialized, then before reinitializing, it prjfree() should be used to free any memory that may have been allocated to store an error message. A memory leak may otherwise result.

Parameters

```
out prj Projection parameters.
```

Returns

Status return value:

- · 0: Success.
- 1: Null prjprm pointer passed.

prjfree()

Destructor for the prjprm struct.

prifree() frees any memory that may have been allocated to store an error message in the priprm struct.

Parameters

```
in prj Projection parameters.
```

Returns

Status return value:

- 0: Success.
- 1: Null prjprm pointer passed.

prjsize()

```
int prjsize (  {\rm const\ struct\ prjprm\ *\ prj,}  int sizes[2] )
```

Compute the size of a prjprm struct.

prjsize() computes the full size of a prjprm struct, including allocated memory.

in	prj	Projection parameters.
		If NULL, the base size of the struct and the allocated size are both set to zero.
out	sizes	The first element is the base size of the struct as returned by sizeof(struct prjprm). The second element is the total allocated size, in bytes. This figure includes memory allocated for the constituent struct, prjprm::err.
		It is not an error for the struct not to have been set up via prjset().

Returns

Status return value:

• 0: Success.

prjenq()

enquire about the state of a prjprm struct.

prjenq() may be used to obtain information about the state of a prjprm struct. The function returns a true/false answer for the enquiry asked.

Parameters

in <i>prj</i> Projection parameters.	
in enquiry Enquiry according to the following para	ameters:
PRJENQ_SET: the struct has be	een set up by prjset().
PRJENQ_BYP: the struct is in b	ypass mode (see prjset()).

Returns

Enquiry result:

- 0: No.
- 1: Yes.

prjprt()

```
int prjprt ( {\tt const\ struct\ prjprm\ *\ prj\ )}
```

Print routine for the prjprm struct.

prjprt() prints the contents of a prjprm struct using wcsprintf(). Mainly intended for diagnostic purposes.

in <i>prj</i>	Projection parameters.
---------------	------------------------

Returns

Status return value:

- 0: Success.
- 1: Null prjprm pointer passed.

prjperr()

Print error messages from a prjprm struct.

prjperr() prints the error message(s) (if any) stored in a **prjprm** struct. If there are no errors then nothing is printed. It uses wcserr_prt(), q.v.

Parameters

in	prj	Projection parameters.
in	prefix	If non-NULL, each output line will be prefixed with this string.

Returns

Status return value:

- 0: Success.
- 1: Null prjprm pointer passed.

prjbchk()

Bounds checking on native coordinates.

prjbchk() performs bounds checking on native spherical coordinates. As returned by the deprojection (x2s) routines, native longitude is expected to lie in the closed interval $[-180^{\circ}, 180^{\circ}]$, with latitude in $[-90^{\circ}, 90^{\circ}]$.

A tolerance may be specified to provide a small allowance for numerical imprecision. Values that lie outside the allowed range by not more than the specified tolerance will be adjusted back into range.

If prjprm::bounds&4 is set, as it is by prjini(), then **prjbchk**() will be invoked automatically by the Cartesian-to-spherical deprojection (x2s) routines with an appropriate tolerance set for each projection.

in	tol Tolerance for the bounds check [deg].	
in	nphi,ntheta	Vector lengths.
in	spt	Vector stride.
in,out	phi,theta	Native longitude and latitude (ϕ,θ) [deg].
out	stat	Status value for each vector element:
		• 0: Valid value of (ϕ,θ) . • 1: Invalid value.

Returns

Status return value:

- · 0: Success.
- 1: One or more of the (ϕ, θ) coordinates were, invalid, as indicated by the stat vector.

prjset()

```
int prjset ( {\tt struct\ prjprm\ *\ prj\ )}
```

Generic setup routine for the prjprm struct.

prjset() sets up a prjprm struct according to information supplied within it.

The one important distinction between **prjset**() and the setup routines for the specific projections is that the projection code must be defined in the **prjprm** struct in order for **prjset**() to identify the required projection. Once **prjset**() has initialized the **prjprm** struct, **prjx2s**() and **prjs2x**() use the pointers to the specific projection and deprojection routines contained therein.

Note that this routine need not be called directly; it will be invoked by prjx2s() and prjs2x() if prj.flag is anything other than a predefined magic value.

prjset() normally operates regardless of the value of prjprm::flag; i.e. even if a struct was previously set up it will be reset unconditionally. However, a prjprm struct may be put into "bypass" mode by invoking **prjset**() initially with prjprm::flag == 1 (rather than 0). **prjset**() will return immediately if invoked on a struct in that state. To take a struct out of bypass mode, simply reset prjprm::flag to zero. See also prjenq().

Parameters

in,out	prj	Projection parameters.
--------	-----	------------------------

Returns

Status return value:

- 0: Success.
- 1: Null prjprm pointer passed.
- 2: Invalid projection parameters.

For returns > 1, a detailed error message is set in priprm::err if enabled, see wcserr_enable().

prjx2s()

Generic Cartesian-to-spherical deprojection.

Deproject Cartesian (x, y) coordinates in the plane of projection to native spherical coordinates (ϕ, θ) .

The projection is that specified by prjprm::code.

Parameters

in,out	prj	Projection parameters.
in	nx,ny	Vector lengths.
in	sxy,spt	Vector strides.
in	x,y	Projected coordinates.
out	phi,theta	Longitude and latitude (ϕ, θ) of the projected point in native spherical coordinates [deg].
out	stat	Status value for each vector element:
		• 0: Success.
		• 1: Invalid value of (x,y) .

Returns

Status return value:

- 0: Success.
- 1: Null prjprm pointer passed.
- 2: Invalid projection parameters.
- 3: One or more of the (x, y) coordinates were invalid, as indicated by the stat vector.

For returns > 1, a detailed error message is set in prjprm::err if enabled, see wcserr_enable().

prjs2x()

Generic spherical-to-Cartesian projection.

Project native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of projection.

The projection is that specified by prjprm::code.

in,out	prj	Projection parameters.
in	nphi,ntheta	Vector lengths.
in	spt,sxy	Vector strides.
in	phi,theta	Longitude and latitude (ϕ,θ) of the projected point in native spherical coordinates [deg].
out	x,y	Projected coordinates.
out	stat	Status value for each vector element: $ \bullet \ 0 \colon \text{Success.} $ $ \bullet \ 1 \colon \text{Invalid value of } (\phi, \theta). $

Returns

Status return value:

- 0: Success.
- 1: Null prjprm pointer passed.
- 2: Invalid projection parameters.
- 4: One or more of the (ϕ,θ) coordinates were, invalid, as indicated by the stat vector.

For returns > 1, a detailed error message is set in prjprm::err if enabled, see wcserr_enable().

azpset()

```
int azpset ( {\tt struct\ prjprm\ *\ prj\ )}
```

Set up a prjprm struct for the zenithal/azimuthal perspective (AZP) projection.

azpset() sets up a prjprm struct for a zenithal/azimuthal perspective (AZP) projection.

See prjset() for a description of the API.

azpx2s()

Cartesian-to-spherical transformation for the zenithal/azimuthal perspective (AZP) projection.

azpx2s() deprojects Cartesian (x,y) coordinates in the plane of a **zenithal**/azimuthal perspective (AZP) projection to native spherical coordinates (ϕ,θ) .

See prjx2s() for a description of the API.

azps2x()

Spherical-to-Cartesian transformation for the zenithal/azimuthal perspective (AZP) projection.

azps2x() projects native spherical coordinates (ϕ,θ) to Cartesian (x,y) coordinates in the plane of a zenithal/azimuthal perspective (AZP) projection.

See prjs2x() for a description of the API.

szpset()

```
int szpset ( {\tt struct\ prjprm\ *\ prj\ )}
```

Set up a priprm struct for the slant zenithal perspective (SZP) projection.

szpset() sets up a prjprm struct for a slant zenithal perspective (SZP) projection.

See prjset() for a description of the API.

szpx2s()

```
int szpx2s (
PRJX2S_ARGS )
```

Cartesian-to-spherical transformation for the slant zenithal perspective (SZP) projection.

szpx2s() deprojects Cartesian (x,y) coordinates in the plane of a slant zenithal perspective (SZP) projection to native spherical coordinates (ϕ,θ) .

See prjx2s() for a description of the API.

szps2x()

```
int szps2x (
PRJS2X ARGS )
```

Spherical-to-Cartesian transformation for the slant zenithal perspective (SZP) projection.

szps2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of a **slant zenithal** perspective (SZP) projection.

See prjs2x() for a description of the API.

tanset()

```
int tanset ( {\tt struct\ prjprm\ *\ prj\ )}
```

Set up a prjprm struct for the **gnomonic (TAN)** projection.

tanset() sets up a priprm struct for a gnomonic (TAN) projection.

See priset() for a description of the API.

tanx2s()

Cartesian-to-spherical transformation for the **gnomonic (TAN)** projection.

tanx2s() deprojects Cartesian (x,y) coordinates in the plane of a **gnomonic (TAN)** projection to native spherical coordinates (ϕ,θ) .

See prjx2s() for a description of the API.

tans2x()

Spherical-to-Cartesian transformation for the gnomonic (TAN) projection.

tans2x() projects native spherical coordinates (ϕ,θ) to Cartesian (x,y) coordinates in the plane of a **gnomonic** (TAN) projection.

See prjs2x() for a description of the API.

stgset()

Set up a prjprm struct for the **stereographic (STG)** projection.

stgset() sets up a prjprm struct for a stereographic (STG) projection.

See prjset() for a description of the API.

stgx2s()

Cartesian-to-spherical transformation for the **stereographic (STG)** projection.

stgx2s() deprojects Cartesian (x,y) coordinates in the plane of a **stereographic (STG)** projection to native spherical coordinates (ϕ,θ) .

See prix2s() for a description of the API.

stgs2x()

```
int stgs2x (
PRJS2X_ARGS )
```

Spherical-to-Cartesian transformation for the **stereographic (STG)** projection.

stgs2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of a **stereographic** (STG) projection.

See prjs2x() for a description of the API.

sinset()

Set up a prjprm struct for the orthographic/synthesis (SIN) projection.

stgset() sets up a prjprm struct for an orthographic/synthesis (SIN) projection.

See prjset() for a description of the API.

sinx2s()

```
int sinx2s (
PRJX2S_ARGS )
```

Cartesian-to-spherical transformation for the orthographic/synthesis (SIN) projection.

sinx2s() deprojects Cartesian (x,y) coordinates in the plane of an orthographic/synthesis (SIN) projection to native spherical coordinates (ϕ,θ) .

See prjx2s() for a description of the API.

sins2x()

Spherical-to-Cartesian transformation for the orthographic/synthesis (SIN) projection.

sins2x() projects native spherical coordinates (ϕ,θ) to Cartesian (x,y) coordinates in the plane of an **orthographic/synthesis (SIN)** projection.

See prjs2x() for a description of the API.

arcset()

```
int arcset ( {\tt struct\ prjprm\ *\ prj\ )}
```

Set up a priprm struct for the zenithal/azimuthal equidistant (ARC) projection.

arcset() sets up a prjprm struct for a zenithal/azimuthal equidistant (ARC) projection.

See prjset() for a description of the API.

arcx2s()

```
int arcx2s ( PRJX2S_ARGS )
```

Cartesian-to-spherical transformation for the zenithal/azimuthal equidistant (ARC) projection.

arcx2s() deprojects Cartesian (x,y) coordinates in the plane of a zenithal/azimuthal equidistant (ARC) projection to native spherical coordinates (ϕ,θ) .

See prjx2s() for a description of the API.

arcs2x()

```
int arcs2x (
PRJS2X ARGS )
```

Spherical-to-Cartesian transformation for the zenithal/azimuthal equidistant (ARC) projection.

arcs2x() projects native spherical coordinates (ϕ,θ) to Cartesian (x,y) coordinates in the plane of a zenithal/azimuthal equidistant (ARC) projection.

See prjs2x() for a description of the API.

zpnset()

```
int zpnset ( {\tt struct\ prjprm\ *\ prj\ )}
```

Set up a prjprm struct for the zenithal/azimuthal polynomial (ZPN) projection.

zpnset() sets up a priprm struct for a zenithal/azimuthal polynomial (ZPN) projection.

See priset() for a description of the API.

zpnx2s()

Cartesian-to-spherical transformation for the zenithal/azimuthal polynomial (ZPN) projection.

zpnx2s() deprojects Cartesian (x, y) coordinates in the plane of a **zenithal/azimuthal polynomial (ZPN)** projection to native spherical coordinates (ϕ, θ) .

See prjx2s() for a description of the API.

zpns2x()

Spherical-to-Cartesian transformation for the zenithal/azimuthal polynomial (ZPN) projection.

 $\mathbf{zpns2x}()$ projects native spherical coordinates (ϕ,θ) to Cartesian (x,y) coordinates in the plane of a $\mathbf{zenithal/azimuthal\ polynomial\ (ZPN)}$ projection.

See prjs2x() for a description of the API.

zeaset()

```
int zeaset ( {\tt struct\ prjprm\ *\ prj\ )}
```

Set up a prjprm struct for the zenithal/azimuthal equal area (ZEA) projection.

zeaset() sets up a prjprm struct for a zenithal/azimuthal equal area (ZEA) projection.

See prjset() for a description of the API.

zeax2s()

Cartesian-to-spherical transformation for the zenithal/azimuthal equal area (ZEA) projection.

zeax2s() deprojects Cartesian (x, y) coordinates in the plane of a **zenithal**/azimuthal equal area (**ZEA**) projection to native spherical coordinates (ϕ, θ) .

See prix2s() for a description of the API.

zeas2x()

Spherical-to-Cartesian transformation for the zenithal/azimuthal equal area (ZEA) projection.

 $\mathbf{zeas2x}()$ projects native spherical coordinates (ϕ,θ) to Cartesian (x,y) coordinates in the plane of a $\mathbf{zenithal/azimuthal}$ equal area (ZEA) projection.

See prjs2x() for a description of the API.

airset()

```
int airset ( {\tt struct\ prjprm\ *\ prj\ )}
```

Set up a prjprm struct for Airy's (AIR) projection.

airset() sets up a prjprm struct for an Airy (AIR) projection.

See prjset() for a description of the API.

airx2s()

```
int airx2s (
PRJX2S_ARGS )
```

Cartesian-to-spherical transformation for Airy's (AIR) projection.

airx2s() deprojects Cartesian (x,y) coordinates in the plane of an **Airy (AIR)** projection to native spherical coordinates (ϕ,θ) .

See prjx2s() for a description of the API.

airs2x()

Spherical-to-Cartesian transformation for Airy's (AIR) projection.

airs2x() projects native spherical coordinates (ϕ,θ) to Cartesian (x,y) coordinates in the plane of an Airy (AIR) projection.

See prjs2x() for a description of the API.

cypset()

```
int cypset ( {\tt struct\ prjprm\ *\ prj\ )}
```

Set up a prjprm struct for the **cylindrical perspective (CYP)** projection.

cypset() sets up a priprm struct for a cylindrical perspective (CYP) projection.

See prjset() for a description of the API.

cypx2s()

```
int cypx2s (
PRJX2S_ARGS )
```

Cartesian-to-spherical transformation for the cylindrical perspective (CYP) projection.

cypx2s() deprojects Cartesian (x,y) coordinates in the plane of a **cylindrical perspective (CYP)** projection to native spherical coordinates (ϕ,θ) .

See prjx2s() for a description of the API.

cyps2x()

```
int cyps2x ( PRJS2X_ARGS )
```

Spherical-to-Cartesian transformation for the cylindrical perspective (CYP) projection.

cyps2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of a cylindrical perspective (CYP) projection.

See prjs2x() for a description of the API.

ceaset()

```
int ceaset ( {\tt struct\ prjprm\ *\ prj\ )}
```

Set up a prjprm struct for the cylindrical equal area (CEA) projection.

ceaset() sets up a priprm struct for a cylindrical equal area (CEA) projection.

See priset() for a description of the API.

ceax2s()

Cartesian-to-spherical transformation for the cylindrical equal area (CEA) projection.

ceax2s() deprojects Cartesian (x,y) coordinates in the plane of a cylindrical equal area (CEA) projection to native spherical coordinates (ϕ,θ) .

See prjx2s() for a description of the API.

ceas2x()

Spherical-to-Cartesian transformation for the cylindrical equal area (CEA) projection.

ceas2x() projects native spherical coordinates (ϕ,θ) to Cartesian (x,y) coordinates in the plane of a **cylindrical** equal area (CEA) projection.

See prjs2x() for a description of the API.

carset()

```
int carset ( {\tt struct\ prjprm\ *\ prj\ )}
```

Set up a prjprm struct for the plate carrée (CAR) projection.

carset() sets up a prjprm struct for a plate carrée (CAR) projection.

See prjset() for a description of the API.

carx2s()

Cartesian-to-spherical transformation for the plate carrée (CAR) projection.

carx2s() deprojects Cartesian (x,y) coordinates in the plane of a **plate carrée (CAR)** projection to native spherical coordinates (ϕ,θ) .

See prix2s() for a description of the API.

cars2x()

```
int cars2x (
PRJS2X_ARGS )
```

Spherical-to-Cartesian transformation for the plate carrée (CAR) projection.

cars2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of a **plate carrée** (CAR) projection.

See prjs2x() for a description of the API.

merset()

```
int merset ( {\tt struct\ prjprm\ *\ prj\ )}
```

Set up a prjprm struct for Mercator's (MER) projection.

merset() sets up a prjprm struct for a Mercator (MER) projection.

See prjset() for a description of the API.

merx2s()

```
int merx2s (
PRJX2S_ARGS )
```

Cartesian-to-spherical transformation for Mercator's (MER) projection.

merx2s() deprojects Cartesian (x,y) coordinates in the plane of a **Mercator (MER)** projection to native spherical coordinates (ϕ,θ) .

See prjx2s() for a description of the API.

mers2x()

Spherical-to-Cartesian transformation for **Mercator's (MER)** projection.

mers2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of a **Mercator** (MER) projection.

See prjs2x() for a description of the API.

sflset()

```
int sflset ( {\tt struct\ prjprm\ *\ prj\ )}
```

Set up a prjprm struct for the Sanson-Flamsteed (SFL) projection.

sflset() sets up a prjprm struct for a Sanson-Flamsteed (SFL) projection.

See prjset() for a description of the API.

sflx2s()

```
int sflx2s (
PRJX2S_ARGS )
```

Cartesian-to-spherical transformation for the Sanson-Flamsteed (SFL) projection.

sflx2s() deprojects Cartesian (x,y) coordinates in the plane of a **Sanson-Flamsteed (SFL)** projection to native spherical coordinates (ϕ,θ) .

See prjx2s() for a description of the API.

sfls2x()

```
int sfls2x (
PRJS2X_ARGS )
```

Spherical-to-Cartesian transformation for the Sanson-Flamsteed (SFL) projection.

sfls2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of a **Sanson**- \leftarrow **Flamsteed (SFL)** projection.

See prjs2x() for a description of the API.

parset()

```
int parset ( {\tt struct\ prjprm\ *\ prj\ )}
```

Set up a prjprm struct for the parabolic (PAR) projection.

parset() sets up a priprm struct for a parabolic (PAR) projection.

See priset() for a description of the API.

parx2s()

Cartesian-to-spherical transformation for the parabolic (PAR) projection.

parx2s() deprojects Cartesian (x,y) coordinates in the plane of a **parabolic (PAR)** projection to native spherical coordinates (ϕ,θ) .

See prjx2s() for a description of the API.

pars2x()

Spherical-to-Cartesian transformation for the parabolic (PAR) projection.

pars2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of a **parabolic** (PAR) projection.

See prjs2x() for a description of the API.

molset()

```
int molset ( {\tt struct\ prjprm\ *\ prj\ )}
```

Set up a prjprm struct for **Mollweide's (MOL)** projection.

molset() sets up a prjprm struct for a Mollweide (MOL) projection.

See prjset() for a description of the API.

molx2s()

Cartesian-to-spherical transformation for Mollweide's (MOL) projection.

molx2s() deprojects Cartesian (x,y) coordinates in the plane of a **Mollweide (MOL)** projection to native spherical coordinates (ϕ,θ) .

See prix2s() for a description of the API.

mols2x()

Spherical-to-Cartesian transformation for Mollweide's (MOL) projection.

mols2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of a **Mollweide** (MOL) projection.

See prjs2x() for a description of the API.

aitset()

Set up a prjprm struct for the **Hammer-Aitoff (AIT)** projection.

aitset() sets up a prjprm struct for a Hammer-Aitoff (AIT) projection.

See prjset() for a description of the API.

aitx2s()

Cartesian-to-spherical transformation for the Hammer-Aitoff (AIT) projection.

aitx2s() deprojects Cartesian (x,y) coordinates in the plane of a **Hammer-Aitoff (AIT)** projection to native spherical coordinates (ϕ,θ) .

See prjx2s() for a description of the API.

aits2x()

Spherical-to-Cartesian transformation for the Hammer-Aitoff (AIT) projection.

aits2x() projects native spherical coordinates (ϕ,θ) to Cartesian (x,y) coordinates in the plane of a **Hammer-Aitoff** (AIT) projection.

See prjs2x() for a description of the API.

copset()

```
int copset ( {\tt struct\ prjprm\ *\ prj\ )}
```

Set up a priprm struct for the **conic perspective (COP)** projection.

copset() sets up a **prjprm** struct for a **conic perspective** (COP) projection.

See prjset() for a description of the API.

copx2s()

Cartesian-to-spherical transformation for the conic perspective (COP) projection.

copx2s() deprojects Cartesian (x,y) coordinates in the plane of a **conic perspective (COP)** projection to native spherical coordinates (ϕ,θ) .

See prjx2s() for a description of the API.

cops2x()

```
int cops2x (
PRJS2X_ARGS )
```

Spherical-to-Cartesian transformation for the conic perspective (COP) projection.

 $\operatorname{cops2x}()$ projects native spherical coordinates (ϕ,θ) to Cartesian (x,y) coordinates in the plane of a **conic perspective (COP)** projection.

See prjs2x() for a description of the API.

coeset()

```
int coeset ( {\tt struct\ prjprm\ *\ prj\ )}
```

Set up a prjprm struct for the conic equal area (COE) projection.

coeset() sets up a priprm struct for a conic equal area (COE) projection.

See priset() for a description of the API.

coex2s()

Cartesian-to-spherical transformation for the **conic equal area (COE)** projection.

coex2s() deprojects Cartesian (x,y) coordinates in the plane of a **conic equal area (COE)** projection to native spherical coordinates (ϕ,θ) .

See prjx2s() for a description of the API.

coes2x()

Spherical-to-Cartesian transformation for the ${f conic}$ equal area (COE) projection.

 $\mathbf{coes2x}()$ projects native spherical coordinates (ϕ,θ) to Cartesian (x,y) coordinates in the plane of a **conic equal** area (COE) projection.

See prjs2x() for a description of the API.

codset()

```
int codset ( {\tt struct\ prjprm\ *\ prj\ )}
```

Set up a priprm struct for the **conic equidistant (COD)** projection.

codset() sets up a prjprm struct for a conic equidistant (COD) projection.

See prjset() for a description of the API.

codx2s()

Cartesian-to-spherical transformation for the conic equidistant (COD) projection.

 $\operatorname{codx2s}()$ deprojects Cartesian (x,y) coordinates in the plane of a conic equidistant (COD) projection to native spherical coordinates (ϕ,θ) .

See prix2s() for a description of the API.

cods2x()

```
int cods2x (
PRJS2X ARGS )
```

Spherical-to-Cartesian transformation for the **conic equidistant (COD)** projection.

 $\operatorname{cods2x}()$ projects native spherical coordinates (ϕ,θ) to Cartesian (x,y) coordinates in the plane of a **conic** equidistant (COD) projection.

See prjs2x() for a description of the API.

cooset()

```
int cooset ( {\tt struct\ prjprm\ *\ prj\ )}
```

Set up a prjprm struct for the **conic orthomorphic (COO)** projection.

cooset() sets up a prjprm struct for a conic orthomorphic (COO) projection.

See prjset() for a description of the API.

coox2s()

```
int coox2s (
PRJX2S_ARGS )
```

Cartesian-to-spherical transformation for the conic orthomorphic (COO) projection.

 $\mathbf{coox2s}()$ deprojects Cartesian (x,y) coordinates in the plane of a \mathbf{conic} orthomorphic (COO) projection to native spherical coordinates (ϕ,θ) .

See prjx2s() for a description of the API.

coos2x()

```
int coos2x ( PRJS2X_ARGS )
```

Spherical-to-Cartesian transformation for the conic orthomorphic (COO) projection.

 $\mathbf{coos2x}()$ projects native spherical coordinates (ϕ,θ) to Cartesian (x,y) coordinates in the plane of a **conic orthomorphic (COO)** projection.

See prjs2x() for a description of the API.

bonset()

```
int bonset ( {\tt struct\ prjprm\ *\ prj\ )}
```

Set up a prjprm struct for **Bonne's (BON)** projection.

bonset() sets up a prjprm struct for a Bonne (BON) projection.

See prjset() for a description of the API.

bonx2s()

Cartesian-to-spherical transformation for Bonne's (BON) projection.

bonx2s() deprojects Cartesian (x,y) coordinates in the plane of a **Bonne** (BON) projection to native spherical coordinates (ϕ,θ) .

See prjx2s() for a description of the API.

bons2x()

```
int bons2x (
PRJS2X_ARGS )
```

Spherical-to-Cartesian transformation for Bonne's (BON) projection.

bons2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of a **Bonne (BON)** projection.

See prjs2x() for a description of the API.

pcoset()

```
int pcoset ( {\tt struct\ prjprm\ *\ prj\ )}
```

Set up a prjprm struct for the **polyconic (PCO)** projection.

pcoset() sets up a priprm struct for a polyconic (PCO) projection.

See priset() for a description of the API.

pcox2s()

Cartesian-to-spherical transformation for the polyconic (PCO) projection.

pcox2s() deprojects Cartesian (x,y) coordinates in the plane of a **polyconic (PCO)** projection to native spherical coordinates (ϕ,θ) .

See prjx2s() for a description of the API.

pcos2x()

```
int pcos2x (
PRJS2X_ARGS )
```

Spherical-to-Cartesian transformation for the **polyconic (PCO)** projection.

 $\mathbf{pcos2x}()$ projects native spherical coordinates (ϕ,θ) to Cartesian (x,y) coordinates in the plane of a $\mathbf{polyconic}$ (PCO) projection.

See prjs2x() for a description of the API.

tscset()

Set up a prjprm struct for the tangential spherical cube (TSC) projection.

tscset() sets up a prjprm struct for a tangential spherical cube (TSC) projection.

See prjset() for a description of the API.

tscx2s()

Cartesian-to-spherical transformation for the tangential spherical cube (TSC) projection.

tscx2s() deprojects Cartesian (x,y) coordinates in the plane of a **tangential spherical cube (TSC)** projection to native spherical coordinates (ϕ,θ) .

See prix2s() for a description of the API.

tscs2x()

```
int tscs2x (
PRJS2X_ARGS )
```

Spherical-to-Cartesian transformation for the tangential spherical cube (TSC) projection.

tscs2x() projects native spherical coordinates (ϕ,θ) to Cartesian (x,y) coordinates in the plane of a tangential spherical cube (TSC) projection.

See prjs2x() for a description of the API.

cscset()

Set up a prjprm struct for the COBE spherical cube (CSC) projection.

cscset() sets up a prjprm struct for a COBE spherical cube (CSC) projection.

See prjset() for a description of the API.

cscx2s()

```
int cscx2s ( PRJX2S_ARGS )
```

Cartesian-to-spherical transformation for the COBE spherical cube (CSC) projection.

cscx2s() deprojects Cartesian (x,y) coordinates in the plane of a **COBE spherical cube (CSC)** projection to native spherical coordinates (ϕ,θ) .

See prjx2s() for a description of the API.

cscs2x()

Spherical-to-Cartesian transformation for the **COBE spherical cube (CSC)** projection.

 $\mathbf{cscs2x}()$ projects native spherical coordinates (ϕ,θ) to Cartesian (x,y) coordinates in the plane of a **COBE spherical cube (CSC)** projection.

See prjs2x() for a description of the API.

qscset()

```
int qscset ( {\tt struct\ prjprm\ *\ prj\ )}
```

Set up a prjprm struct for the quadrilateralized spherical cube (QSC) projection.

qscset() sets up a priprm struct for a quadrilateralized spherical cube (QSC) projection.

See prjset() for a description of the API.

qscx2s()

Cartesian-to-spherical transformation for the quadrilateralized spherical cube (QSC) projection.

qscx2s() deprojects Cartesian (x,y) coordinates in the plane of a **quadrilateralized spherical cube (QSC)** projection to native spherical coordinates (ϕ,θ) .

See prjx2s() for a description of the API.

qscs2x()

```
int qscs2x (
PRJS2X ARGS )
```

Spherical-to-Cartesian transformation for the quadrilateralized spherical cube (QSC) projection.

qscs2x() projects native spherical coordinates (ϕ,θ) to Cartesian (x,y) coordinates in the plane of a quadrilateralized spherical cube (QSC) projection.

See prjs2x() for a description of the API.

hpxset()

```
int hpxset ( {\tt struct\ prjprm\ *\ prj\ )}
```

Set up a prjprm struct for the **HEALPix** (**HPX**) projection.

hpxset() sets up a **prjprm** struct for a **HEALPix** (**HPX**) projection.

See prjset() for a description of the API.

hpxx2s()

```
int hpxx2s ( PRJX2S_ARGS )
```

Cartesian-to-spherical transformation for the **HEALPix** (**HPX**) projection.

hpxx2s() deprojects Cartesian (x,y) coordinates in the plane of a **HEALPix (HPX)** projection to native spherical coordinates (ϕ,θ) .

See prjx2s() for a description of the API.

hpxs2x()

```
int hpxs2x (
PRJS2X_ARGS )
```

Spherical-to-Cartesian transformation for the **HEALPix (HPX)** projection.

hpxs2x() projects native spherical coordinates (ϕ, θ) to Cartesian (x, y) coordinates in the plane of a **HEALPix** (**HPX**) projection.

See prjs2x() for a description of the API.

xphset()

int xphs2x (

PRJS2X_ARGS)

6.13.5 Variable Documentation

prj_errmsg

```
const char * prj_errmsg[] [extern]
```

Status return messages.

Error messages to match the status value returned from each function.

CONIC

```
const int CONIC [extern]
```

Identifier for conic projections.

Identifier for conic projections, see prjprm::category.

CONVENTIONAL

```
const int CONVENTIONAL
```

Identifier for conventional projections.

Identifier for conventional projections, see prjprm::category.

CYLINDRICAL

```
const int CYLINDRICAL
```

Identifier for cylindrical projections.

Identifier for cylindrical projections, see prjprm::category.

POLYCONIC

```
const int POLYCONIC
```

Identifier for polyconic projections.

Identifier for polyconic projections, see prjprm::category.

PSEUDOCYLINDRICAL

```
const int PSEUDOCYLINDRICAL
```

Identifier for pseudocylindrical projections.

Identifier for pseudocylindrical projections, see prjprm::category.

QUADCUBE

```
const int QUADCUBE
```

Identifier for quadcube projections.

Identifier for quadcube projections, see prjprm::category.

ZENITHAL

```
const int ZENITHAL
```

Identifier for zenithal/azimuthal projections.

Identifier for zenithal/azimuthal projections, see prjprm::category.

HEALPIX

```
const int HEALPIX
```

Identifier for the HEALPix projection.

Identifier for the HEALPix projection, see prjprm::category.

prj_categories

```
const char prj_categories[9][32] [extern]
```

Projection categories.

Names of the projection categories, all in lower-case except for "HEALPix".

Provided for information only, not used by the projection routines.

prj_ncode

```
const int prj_ncode [extern]
```

The number of recognized three-letter projection codes.

The number of recognized three-letter projection codes (currently 27), see prj_codes.

prj_codes

```
const char prj_codes[27][4] [extern]
```

Recognized three-letter projection codes.

List of all recognized three-letter projection codes (currently 27), e.g. SIN, TAN, etc.

6.14 prj.h

00046 *
00047 \star These routines are based on the prjprm struct which contains all information
00048 \star needed for the computations. The struct contains some members that must be
00049 * set by the user, and others that are maintained by these routines, somewhat
00050 * like a C++ class but with no encapsulation.
00051 *
00052 * Routine prjini() is provided to initialize the prjprm struct with default
00053 \star values, prjfree() reclaims any memory that may have been allocated to store
00054 \star an error message, prjsize() computes its total size including allocated
00055 \star memory, prjeng() returns information about the state of the struct, and
00056 \star prjprt() prints its contents.
00057 *
00058 \star prjperr() prints the error message(s) (if any) stored in a prjprm struct.
00059 * prjbchk() performs bounds checking on native spherical coordinates.
00060 *
00061 \star Setup routines for each projection with names of the form ???set(), where 00062 \star "???" is the down-cased three-letter projection code, compute intermediate
00063 \star values in the prjprm struct from parameters in it that were supplied by the
00064 * user.
               The struct always needs to be set by the projection's setup routine
00065 \star but that need not be called explicitly - refer to the explanation of
00066 * prjprm::flag.
00067 *
00068 * Each map projection is implemented via separate functions for the spherical
00069 * projection, ???s2x(), and deprojection, ???x2s().
00071 * A set of driver routines, prjset(), prjx2s(), and prjs2x(), provides a
00072 \star generic interface to the specific projection routines which they invoke
00073 \star via pointers-to-functions stored in the prjprm struct.
00074 *
00075 * In summary, the routines are:
00076 *
         - prjini()
                                     Initialization routine for the prjprm struct.
                                     Reclaim memory allocated for error messages.
00077 *
         - prjfree()
                                     Compute total size of a prjprm struct.
00078 *
         - prjsize()
00079 *
         - prjprt()
                                     Print a prjprm struct.
00080 *
                                     Print error message (if any).
         - prjperr()
00081 *
         - prjbchk()
                                     Bounds checking on native coordinates.
00082 *

00111 *
          - hpxset(), hpxx2s(), hpxs2x():
                                              HPX (HEALPix)
00112 *
         - xphset(), xphx2s(), xphs2x():
                                              XPH (HEALPix polar, aka "butterfly")
00113 *
00114 * Argument checking (projection routines):
00115 *
00116 \star The values of phi and theta (the native longitude and latitude) normally lie
00117 \star in the range [-180,180] for phi, and [-90,90] for theta. However, all
00118 \star projection routines will accept any value of phi and will not normalize it.
00119 *
00120 \star The projection routines do not explicitly check that theta lies within the 00121 \star range [-90,90]. They do check for any value of theta that produces an
00122 * invalid argument to the projection equations (e.g. leading to division by
00123 \star zero). The projection routines for AZP, SZP, TAN, SIN, ZPN, and COP also
00124 \star return error 2 if (phi,theta) corresponds to the overlapped (far) side of
00125 * the projection but also return the corresponding value of (x,y). This
00126 \star strict bounds checking may be relaxed at any time by setting 00127 \star prjprm::bounds%2 to 0 (rather than 1); the projections need not be
00128 * reinitialized.
00129 *
00130 * Argument checking (deprojection routines):
00131 * -
00132 * Error checking on the projected coordinates (x,y) is limited to that
00133 \star required to ascertain whether a solution exists. Where a solution does
00134 \star exist, an optional check is made that the value of phi and theta obtained
00135 \star lie within the ranges [-180,180] for phi, and [-90,90] for theta.
00136 \star check, performed by prjbchk(), is enabled by default. It may be disabled by
00137 * setting prjprm::bounds%4 to 0 (rather than 1); the projections need not be
00138 * reinitialized.
00139 *
00141 *
00142 \star No warranty is given for the accuracy of these routines (refer to the
00143 \star copyright notice); intending users must satisfy for themselves their
00144 \star adequacy for the intended purpose. However, closure to a precision of at
00145 \star least 1E-10 degree of longitude and latitude has been verified for typical
00146 \star projection parameters on the 1 degree graticule of native longitude and
00147 \star latitude (to within 5 degrees of any latitude where the projection may
00148 * diverge). Refer to the tprjl.c and tprj2.c test routines that accompany
00149 * this software.
00150 *
00151 *
00152 * prjini() - Default constructor for the prjprm struct
00154 \star prjini() sets all members of a prjprm struct to default values. It should
00155 \star be used to initialize every prjprm struct.
00156 *
00157 * PLEASE NOTE: If the prjprm struct has already been initialized, then before
00158 \star reinitializing, it prjfree() should be used to free any memory that may have
00159 * been allocated to store an error message. A memory leak may otherwise
00160 * result.
00161 *
00162 * Returned:
00163 * prj
                    struct priprm*
00164 *
                               Projection parameters.
00165
00166 * Function return value:
00167 *
                    int
                               Status return value:
00168 *
                                 0: Success.
00169 *
                                  1: Null prjprm pointer passed.
00170 *
```

```
00172 * prjfree() - Destructor for the prjprm struct
00173 *
00174 \star prjfree() frees any memory that may have been allocated to store an error
00175 * message in the prjprm struct.
00176 *
00177 * Given:
00178 * prj
                    struct prjprm*
                               Projection parameters.
00179 *
00180 *
00181 * Function return value:
00182 *
                    int
                               Status return value:
00183 *
                                  0: Success.
00184 *
                                  1: Null prjprm pointer passed.
00185 *
00186 *
00187 * prjsize() - Compute the size of a prjprm struct
00188 *
00189 \star prjsize() computes the full size of a prjprm struct, including allocated
00190 * memory.
00191 *
00192 * Given:
00193 * prj
                   const struct prjprm*
00194 *
                               Projection parameters.
00195 *
00196
                               If NULL, the base size of the struct and the allocated
00197 *
                                size are both set to zero.
00198 *
00199 * Returned:
00200 *
          sizes
                     int[2]
                               The first element is the base size of the struct as
                                returned by sizeof(struct prjprm). The second element is the total allocated size, in bytes. This figure
00201 *
                                is the total allocated size, in bytes. This figure includes memory allocated for the constituent struct,
00202 *
00203 *
00204 *
                                prjprm::err.
00205 *
00206 *
                               It is not an error for the struct not to have been set
00207 *
                               up via prjset().
00209 * Function return value:
00210 *
                            Status return value:
00211 *
                                  0: Success.
00212 *
00213 *
00214 * prjenq() - enquire about the state of a prjprm struct
00216 \star prjenq() may be used to obtain information about the state of a prjprm
00217 \star struct. The function returns a true/false answer for the enquiry asked.
00218 *
00219 * Given:
00220 * prj
                     const struct prjprm*
00221 *
                               Projection parameters.
00222 *
00223 *
         enquiry int
                               Enquiry according to the following parameters:
00224 *
                                  {\tt PRJENQ\_SET:} the struct has been set up by prjset().
00225 *
                                  PRJENQ_BYP: the struct is in bypass mode (see
00226 *
                                              priset()).
00228 * Function return value:
00229 *
                               Enquiry result:
                    int
00230 *
                                  0: No.
00231 *
                                  1: Yes.
00232 *
00233 *
00234 \star prjprt() - Print routine for the prjprm struct
00235 *
00236 \star prjprt() prints the contents of a prjprm struct using wcsprintf(). Mainly
00237 \star intended for diagnostic purposes.
00238 *
00239 * Given:
00240 * prj
                    const struct prjprm*
00241 *
                               Projection parameters.
00242 *
00243 * Function return value:
00244 *
                               Status return value:
                    int
00245 *
                                  0: Success.
00246
                                  1: Null prjprm pointer passed.
00247 *
00248 *
00249 \star prjperr() - Print error messages from a prjprm struct
00250 *
00251 \star prjperr() prints the error message(s) (if any) stored in a prjprm struct.
00252 * If there are no errors then nothing is printed. It uses wcserr_prt(), q.v.
00253 *
00254 * Given:
00255 * prj
                     const struct prjprm*
00256 *
                               Projection parameters.
00257 *
```

```
00258 * prefix
                    const char *
00259 *
                                If non-NULL, each output line will be prefixed with
00260 *
                                 this string.
00261 *
00262 * Function return value:
00263 *
                                 Status return value:
                     int
                                   0: Success.
00265 *
                                   1: Null prjprm pointer passed.
00266 *
00267 *
00268 * prjbchk() - Bounds checking on native coordinates
00269 * -
00270 \star prjbchk() performs bounds checking on native spherical coordinates. As
00271 * returned by the deprojection (x2s) routines, native longitude is expected
00272 \star to lie in the closed interval [-180,180], with latitude in [-90,90].
00273 *
00274 \star A tolerance may be specified to provide a small allowance for numerical 00275 \star imprecision. Values that lie outside the allowed range by not more than
00276 * the specified tolerance will be adjusted back into range.
00277
00278 * If prjprm::bounds&4 is set, as it is by prjini(), then prjbchk() will be
00279 \star invoked automatically by the Cartesian-to-spherical deprojection (x2s)
00280 * routines with an appropriate tolerance set for each projection.
00281 *
00282 * Given:
00283 *
          tol
                     double
                              Tolerance for the bounds check [deg].
00284 *
00285 *
          nphi.
00286 *
          ntheta
                      int
                                Vector lengths.
00287 *
00288 *
          spt
                     int
                                Vector stride.
00289 *
00290 * Given and returned:
00291 *
          phi, theta double[] Native longitude and latitude (phi, theta) [deg].
00292 *
00293 * Returned:
00294 *
          stat
                      int[]
                                Status value for each vector element:
                                   0: Valid value of (phi, theta).
00295 *
00296 *
                                   1: Invalid value.
00297 *
00298 * Function return value:
00299 *
                     int
                                 Status return value:
00300 *
                                   0: Success.
00301 *
                                   1: One or more of the (phi, theta) coordinates
                                       were, invalid, as indicated by the stat vector.
00302 *
00303 *
00304 *
00305 \star prjset() - Generic setup routine for the prjprm struct
00306 * -
00307 \star prjset() sets up a prjprm struct according to information supplied within
00308 * it.
00309 *
00310 \star The one important distinction between prjset() and the setup routines for
00311 \star the specific projections is that the projection code must be defined in the 00312 \star prjprm struct in order for prjset() to identify the required projection.
00313 * Once prjset() has initialized the prjprm struct, prjx2s() and prjs2x() use
00314 * the pointers to the specific projection and deprojection routines contained
00315 * therein.
00316 *
00317 \star Note that this routine need not be called directly; it will be invoked by
00318 * prjx2s() and prjs2x() if prj.flag is anything other than a predefined magic
00319 * value.
00320 *
00321 \star prjset() normally operates regardless of the value of prjprm::flag; i.e.
00322 * even if a struct was previously set up it will be reset unconditionally.
00323 \star However, a prjprm struct may be put into "bypass" mode by invoking prjset()
00324 \star initially with prjprm::flag == 1 (rather than 0). prjset() will return 00325 \star immediately if invoked on a struct in that state. To take a struct out
                                                                To take a struct out of
00326 * bypass mode, simply reset prjprm::flag to zero. See also prjenq().
00327 *
00328 * Given and returned:
00329 * prj struct prjprm*
00330 *
                                Projection parameters.
00331 *
00332 * Function return value:
00333 *
                                 Status return value:
                     int
00334 *
                                   0: Success.
00335 *
                                   1: Null prjprm pointer passed.
00336 *
                                   2: Invalid projection parameters.
00337 *
00338 *
                                 For returns > 1, a detailed error message is set in
00339
                                prjprm::err if enabled, see wcserr_enable().
00340 *
00341 *
00342 * prjx2s() - Generic Cartesian-to-spherical deprojection
00343 *
00344 * Deproject Cartesian (x,v) coordinates in the plane of projection to native
```

```
00345 * spherical coordinates (phi, theta).
00346
00347 * The projection is that specified by prjprm::code.
00348 *
00349 * Given and returned:
00350 * prj
                   struct prjprm*
00351 *
                               Projection parameters.
00352 *
00353 * Given:
00354 *
         nx,ny
                    int
                              Vector lengths.
00355 *
         sxy,spt int
00356 *
                              Vector strides.
00357 *
00358 *
                   const double[]
         X, V
00359 *
                              Projected coordinates.
00360 *
00361 * Returned:
00362 *
         phi,theta double[] Longitude and latitude (phi,theta) of the projected
                               point in native spherical coordinates [deg].
00363 *
00364 *
00365 *
                   int[] Status value for each vector element:
00366 *
                                 0: Success.
00367 *
                                 1: Invalid value of (x,y).
00368 *
00369 * Function return value:
00370 *
                    int
                               Status return value:
00371 *
                                 0: Success.
00372 *
                                 1: Null prjprm pointer passed.
00373 *
                                 2: Invalid projection parameters.
00374 *
                                 3: One or more of the (x,y) coordinates were
00375 *
                                    invalid, as indicated by the stat vector.
00376 *
00377 *
                               For returns > 1, a detailed error message is set in
00378 *
                               prjprm::err if enabled, see wcserr_enable().
00379 *
00380 *
00381 * prjs2x() - Generic spherical-to-Cartesian projection
00382 *
00383 \star Project native spherical coordinates (phi, theta) to Cartesian (x,y)
00384 \star coordinates in the plane of projection.
00385 *
00386 * The projection is that specified by prjprm::code.
00387 *

                              Status value for each vector element:
00462 *
                                 0: Success.
00463 *
                                 1: Invalid value of (x,y).
00464 *
00465 * Function return value:
00466 *
                    int
                               Status return value:
00467 *
                                 0: Success.
00468 *
                                 1: Null prjprm pointer passed.
                                 2: Invalid projection parameters.
00469
00470 *
                                 3: One or more of the (x,y) coordinates were
00471 *
                                    invalid, as indicated by the stat vector.
00472 *
00473 *
                               For returns > 1, a detailed error message is set in
                               prjprm::err if enabled, see wcserr_enable().
00474 *
00475 *
00476
00477 * ???s2x() - Specific spherical-to-Cartesian projection routines
00478 *-
00479 * Transform native spherical coordinates (phi,theta) to (x,y) coordinates in
00480 \star the plane of projection.
00481 *
00482 * Given and returned:
00483 * prj
                   struct prjprm*
00484 *
                               Projection parameters.
00485 *
00486 * Given:
00487 *
         nphi,
00488 *
         ntheta
                              Vector lengths.
00489 *
00490 *
         spt,sxy
                  int
                              Vector strides.
00491 *
         phi,theta const double[]
00492 *
                               Longitude and latitude of the projected point in
00493 *
00494 *
                               native spherical coordinates [deg].
00495 *
00496 * Returned:
00497 * x,y
                    double[] Projected coordinates.
00498 *
00499 *
                              Status value for each vector element:
         stat
                    int[]
00500 *
                                 0: Success.
                                1: Invalid value of (phi, theta).
00501 *
00502 *
00503 * Function return value:
00504 *
                    int
                               Status return value:
00505 *
                                 0: Success.
00506 *
                                 1: Null priprm pointer passed.
00507 *
                                 2: Invalid projection parameters.
00508 *
                                 4: One or more of the (phi, theta) coordinates
00509 *
                                    were, invalid, as indicated by the stat vector.
00510 *
00511 *
                               For returns > 1, a detailed error message is set in
                               prjprm::err if enabled, see wcserr_enable().
00512 *
00514 *
00515 * prjprm struct - Projection parameters
00516 *
00517 \star The prjprm struct contains all information needed to project or deproject
00518 * native spherical coordinates. It consists of certain members that must be
```

```
00519 \star set by the user ("given") and others that are set by the WCSLIB routines
00520 \star ("returned"). Some of the latter are supplied for informational purposes
00521 * while others are for internal use only.
00522 *
00523 *
           int flag
00524 *
             (Given and returned) This flag must be set to zero (or 1, see prjset())
00525 *
             whenever any of the following prjprm members are set or changed:
00526 *
00527 *
                - prjprm::code,
00528 *
               - prjprm::r0,
00529 *
               - prjprm::pv[],
00530 *
               - prjprm::phi0,
00531 *
               - prjprm::theta0.
00532 *
00533 *
             This signals the initialization routine (prjset() or ???set()) to
00534 *
             recompute the returned members of the prjprm struct. flag will then be
00535 *
             reset to indicate that this has been done.
00536 *
             Note that flag need not be reset when priprm::bounds is changed.
00538 *
00539 *
           char code[4]
00540 *
             (Given) Three-letter projection code defined by the FITS standard.
00541 *
00542 *
           double r0
00543 *
             (Given) The radius of the generating sphere for the projection, a linear
             scaling parameter. If this is zero, it will be reset to its default
00544
00545 *
             value of 180/pi (the value for FITS WCS).
00546 *
00547 *
           double pv[30]
00548 *
             (Given) Projection parameters. These correspond to the PVi_ma keywords
             in FITS, so pv[0] is PVi_0a, pv[1] is PVi_1a, etc., where i denotes the latitude-like axis. Many projections use pv[1] (PVi_1a), some also use pv[2] (PVi_2a) and SZP uses pv[3] (PVi_3a). ZPN is currently the only
00549 *
00550 *
00551 *
00552 *
             projection that uses any of the others.
00553 *
00554 *
             Usage of the pv[] array as it applies to each projection is described in
00555 *
             the prologue to each trio of projection routines in prj.c.
00556 *
00557 *
           double phi0
00558 *
             (Given) The native longitude, phi_0 [deg], and ...
00559 *
           double theta0
             (Given) ... the native latitude, theta_0 [deg], of the reference point, i.e. the point (x,y)=(0,0). If undefined (set to a magic value by prjini()) the initialization routine will set this to a
00560 *
00561 *
00562 *
00563 *
             projection-specific default.
00564 *
00565 *
           int bounds
00566 *
             (Given) Controls bounds checking. If bounds \&1 then enable strict bounds
             checking for the spherical-to-Cartesian (s2x) transformation for the \,
00567 *
00568 *
             AZP, SZP, TAN, SIN, ZPN, and COP projections. If bounds&2 then enable
00569 *
             strict bounds checking for the Cartesian-to-spherical transformation
             (x2s) for the HPX and XPH projections. If bounds&4 then the Cartesian-to-spherical transformations (x2s) will invoke prjbchk() to perform
00570 *
00571 *
             bounds checking on the computed native coordinates, with a tolerance set to suit each projection. bounds is set to 7 by prjini() by default
00572 *
00573 *
00574 *
             which enables all checks. Zero it to disable all checking.
00575 *
00576 *
             It is not necessary to reset the prjprm struct (via prjset() or
00577 *
             ???set()) when prjprm::bounds is changed.
00578 *
00579 \star The remaining members of the prjprm struct are maintained by the setup
00580 * routines and must not be modified elsewhere:
00581 *
00582 *
00583 *
             (Returned) Long name of the projection.
00584 *
00585 *
             Provided for information only, not used by the projection routines.
00586 *
00587 *
          int category
00588 *
             (Returned) Projection category matching the value of the relevant global
00589 *
00590 *
             - ZENITHAL,
00591 *
             - CYLINDRICAL.
00592 *
00593 *
             - PSEUDOCYLINDRICAL,
00594 *
             - CONVENTIONAL,
00595 *
             - CONIC,
00596 *
             - POLYCONIC,
             - QUADCUBE, and
00597 *
00598 *
             - HEALPIX.
00599 *
00600 *
             The category name may be identified via the prj_categories character
00601 *
             array, e.g.
00602 *
00603 =
               struct prjprm prj;
00604 =
00605 =
               printf("%s\n", pri categories[pri.category]);
```

```
Provided for information only, not used by the projection routines.
00607 *
00608 *
00609 *
          int pvrange
00610 *
            (Returned) Range of projection parameter indices: 100 times the first
00611 *
            allowed index plus the number of parameters, e.g. TAN is 0 (no parameters), SZP is 103 (1 to 3), and ZPN is 30 (0 to 29).
00612 *
00613 *
00614 *
            Provided for information only, not used by the projection routines.
00615 *
00616 *
          int simplezen
00617 *
            (Returned) True if the projection is a radially-symmetric zenithal
00618 *
            projection.
00619 *
00620 *
            Provided for information only, not used by the projection routines.
00621 *
00622 *
          int equiareal
00623 *
            (Returned) True if the projection is equal area.
00624 *
00625 *
            Provided for information only, not used by the projection routines.
00626 *
00627 *
          int conformal
00628 *
            (Returned) True if the projection is conformal.
00629 *
00630 *
            Provided for information only, not used by the projection routines.
00631 *
00632 *
00633 *
            (Returned) True if the projection can represent the whole sphere in a
00634 *
            finite, non-overlapped mapping.
00635 *
00636 *
            Provided for information only, not used by the projection routines.
00637 *
00638 *
00639 *
            (Returned) True if the projection diverges in latitude.
00640 *
00641 *
            Provided for information only, not used by the projection routines.
00642 *
00643 *
00644 *
            (Returned) The offset in x, and ...
00645 *
          double y0
00646 *
            (Returned) ... the offset in y used to force (x,y) = (0,0) at
00647 *
            (phi_0,theta_0).
00648 *
00649 *
          struct wcserr *err
00650 *
           (Returned) If enabled, when an error status is returned, this struct
00651 *
            contains detailed information about the error, see wcserr_enable().
00652 *
          void *padding
00653 *
00654 *
            (An unused variable inserted for alignment purposes only.)
00655 *
00656 *
          double w[10]
00657 *
            (Returned) Intermediate floating-point values derived from the
00658 *
            projection parameters, cached here to save recomputation.
00659 *
00660 *
            Usage of the w[] array as it applies to each projection is described in
00661 *
            the prologue to each trio of projection routines in prj.c.
00662 *
00663 *
00664 *
           (Returned) Intermediate integer value (used only for the ZPN and HPX
00665 *
            projections).
00666 *
          int (*prjx2s) (PRJX2S_ARGS)
   (Returned) Pointer to the spherical projection ...
00667 *
00668 *
          int (*prjs2x) (PRJ_ARGS)
00669 *
00670 *
            (Returned) ... and deprojection routines.
00671 *
00672 *
00673 * Global variable: const char *prj_errmsg[] - Status return messages
00674 * -
00675 \star Error messages to match the status value returned from each function.
00676 *
00677 *=

 Status return messages.

6.15.1 Detailed Description

Routines in this suite implement the part of the FITS World Coordinate System (WCS) standard that deals with spectral coordinates, as described in

```
"Representations of world coordinates in FITS",
Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061 (WCS Paper I)
"Representations of spectral coordinates in FITS",
Greisen, E.W., Calabretta, M.R., Valdes, F.G., & Allen, S.L.
2006, A&A, 446, 747 (WCS Paper III)
```

These routines define methods to be used for computing spectral world coordinates from intermediate world coordinates (a linear transformation of image pixel coordinates), and vice versa. They are based on the spcprm struct which contains all information needed for the computations. The struct contains some members that must be set by the user, and others that are maintained by these routines, somewhat like a C++ class but with no encapsulation.

Routine spcini() is provided to initialize the spcprm struct with default values, spcfree() reclaims any memory that may have been allocated to store an error message, spcsize() computes its total size including allocated memory, spceng() returns information about the state of the struct, and spcprt() prints its contents.

spcperr() prints the error message(s) (if any) stored in a spcprm struct.

A setup routine, spcset(), computes intermediate values in the spcprm struct from parameters in it that were supplied by the user. The struct always needs to be set up by spcset() but it need not be called explicitly - refer to the explanation of spcprm::flag.

spcx2s() and spcs2x() implement the WCS spectral coordinate transformations. In fact, they are high level driver routines for the lower level spectral coordinate transformation routines described in spx.h.

A number of routines are provided to aid in analysing or synthesising sets of FITS spectral axis keywords:

- spctype() checks a spectral CTYPEia keyword for validity and returns information derived from it.
- Spectral keyword analysis routine spcspxe() computes the values of the X-type spectral variables for the S-type variables supplied.
- Spectral keyword synthesis routine, spcxpse(), computes the S-type variables for the X-types supplied.
- Given a set of spectral keywords, a translation routine, spctrne(), produces the corresponding set for the specified spectral CTYPEia.
- spcaips() translates AIPS-convention spectral CTYPEia and VELREF keyvalues.

Spectral variable types - S, P, and X:

A few words of explanation are necessary regarding spectral variable types in FITS.

Every FITS spectral axis has three associated spectral variables:

S-type: the spectral variable in which coordinates are to be expressed. Each S-type is encoded as four characters and is linearly related to one of four basic types as follows:

F (Frequency):

• 'FREQ': frequency

· 'AFRQ': angular frequency

• 'ENER': photon energy

• 'WAVN': wave number

· 'VRAD': radio velocity

W (Wavelength in vacuo):

· 'WAVE': wavelength

'VOPT': optical velocity

• 'ZOPT': redshift

A (wavelength in Air):

• 'AWAV': wavelength in air

V (Velocity):

· 'VELO': relativistic velocity

• 'BETA': relativistic beta factor

The S-type forms the first four characters of the CTYPEia keyvalue, and CRVALia and CDELTia are expressed as S-type quantities so that they provide a first-order approximation to the S-type variable at the reference point.

Note that 'AFRQ', angular frequency, is additional to the variables defined in WCS Paper III.

P-type: the basic spectral variable (F, W, A, or V) with which the *S*-type variable is associated (see list above).

For non-grism axes, the P-type is encoded as the eighth character of **CTYPE**ia.

X-type: the basic spectral variable (F, W, A, or V) for which the spectral axis is linear, grisms excluded (see below).

For non-grism axes, the X-type is encoded as the sixth character of ${\tt CTYPEia}$.

Grisms: Grism axes have normal S-, and P-types but the axis is linear, not in any spectral variable, but in a special "grism parameter". The X-type spectral variable is either W or A for grisms in vacuo or air respectively, but is encoded as 'w' or 'a' to indicate that an additional transformation is required to convert to or from the grism parameter. The spectral algorithm code for grisms also has a special encoding in CTYPEia, either 'GRI' (in vacuo) or 'GRA' (in air).

In the algorithm chain, the non-linear transformation occurs between the X-type and the P-type variables; the transformation between P-type and S-type variables is always linear.

When the P-type and X-type variables are the same, the spectral axis is linear in the S-type variable and the second four characters of CTYPEia are blank. This can never happen for grism axes.

As an example, correlating radio spectrometers always produce spectra that are regularly gridded in frequency; a redshift scale on such a spectrum is non-linear. The required value of $\mathtt{CTYPEia}$ would be $'\mathtt{ZOPT-F2W'}$, where the desired S-type is $'\mathtt{ZOPT'}$ (redshift), the P-type is necessarily 'W' (wavelength), and the X-type is 'F' (frequency) by the nature of the instrument.

Air-to-vacuum wavelength conversion:

Please refer to the prologue of spx.h for important comments relating to the air-to-vacuum wavelength conversion.

Argument checking:

The input spectral values are only checked for values that would result in floating point exceptions. In particular, negative frequencies and wavelengths are allowed, as are velocities greater than the speed of light. The same is true for the spectral parameters - rest frequency and wavelength.

Accuracy:

No warranty is given for the accuracy of these routines (refer to the copyright notice); intending users must satisfy for themselves their adequacy for the intended purpose. However, closure effectively to within double precision rounding error was demonstrated by test routine tspc.c which accompanies this software.

6.15.2 Macro Definition Documentation

SPCLEN

```
#define SPCLEN (sizeof(struct spcprm)/sizeof(int))
```

Size of the spcprm struct in int units.

Size of the spcprm struct in *int* units, used by the Fortran wrappers.

6.15.4 Function Documentation

spcini()

Default constructor for the spcprm struct.

spcini() sets all members of a spcprm struct to default values. It should be used to initialize every spcprm struct.

PLEASE NOTE: If the spcprm struct has already been initialized, then before reinitializing, it spcfree() should be used to free any memory that may have been allocated to store an error message. A memory leak may otherwise result.

Parameters

in,out	spc	Spectral transformation parameters.
--------	-----	-------------------------------------

Returns

Status return value:

- 0: Success.
- 1: Null spcprm pointer passed.

spcfree()

Destructor for the spcprm struct.

spcfree() frees any memory that may have been allocated to store an error message in the spcprm struct.

in	spc	Spectral transformation parameters.
----	-----	-------------------------------------

Returns

Status return value:

- 0: Success.
- 1: Null spcprm pointer passed.

spcsize()

Compute the size of a spcprm struct.

spcsize() computes the full size of a spcprm struct, including allocated memory.

Parameters

in	spc	Spectral transformation parameters.
		If NULL, the base size of the struct and the allocated size are both set to zero.
out	sizes	The first element is the base size of the struct as returned by sizeof(struct spcprm). The second element is the total allocated size, in bytes. This figure includes memory allocated for the constituent struct, spcprm::err. It is not an error for the struct not to have been set up via spcset().

Returns

Status return value:

• 0: Success.

spcenq()

enquire about the state of a spcprm struct.

spcenq() may be used to obtain information about the state of a spcprm struct. The function returns a true/false answer for the enquiry asked.

in	spc	Spectral transformation parameters.	
in	enquiry	Enquiry according to the following parameters:	
		SPCENQ_MEM: memory in the struct is being managed by WCSLIB (see spcini()).	
		 SPCENQ_SET: the struct has been set up by spcset(). 	
		 SPCENQ_BYP: the struct is in bypass mode (see spcset()). 	
		These may be combined by logical OR, e.g. SPCENQ_MEM SPCENQ_SET. The enquiry result will be the logical AND of the individual results.	

Returns

Enquiry result:

- 0: No.
- 1: Yes.

spcprt()

```
int spcprt ( {\rm const\ struct\ spcprm\ *\ spc\ )}
```

Print routine for the spcprm struct.

spcprt() prints the contents of a spcprm struct using wcsprintf(). Mainly intended for diagnostic purposes.

Parameters

	in	spc	Spectral transformation parameters.	1
--	----	-----	-------------------------------------	---

Returns

Status return value:

- 0: Success.
- 1: Null spcprm pointer passed.

spcperr()

Print error messages from a spcprm struct.

spcperr() prints the error message(s) (if any) stored in a spcprm struct. If there are no errors then nothing is printed. It uses wcserr_prt(), q.v.

Parameters

in	spc	Spectral transformation parameters.
in	prefix	If non-NULL, each output line will be prefixed with this string.

Returns

Status return value:

- 0: Success.
- 1: Null spcprm pointer passed.

spcset()

```
int spcset ( {\tt struct\ spcprm\ *\ spc}\ )
```

Setup routine for the spcprm struct.

spcset() sets up a spcprm struct according to information supplied within it.

Note that this routine need not be called directly; it will be invoked by spcx2s() and spcs2x() if spcprm::flag is anything other than a predefined magic value.

spcset() normally operates regardless of the value of spcprm::flag; i.e. even if a struct was previously set up it will be reset unconditionally. However, a spcprm struct may be put into "bypass" mode by invoking **spcset**() initially with spcprm::flag == 1 (rather than 0). **spcset**() will return immediately if invoked on a struct in that state. To take a struct out of bypass mode, simply reset spcprm::flag to zero. See also spceng().

Parameters

	in,out	spc	Spectral transformation parameters.
--	--------	-----	-------------------------------------

Returns

Status return value:

- 0: Success.
- 1: Null spcprm pointer passed.
- 2: Invalid spectral parameters.

For returns > 1, a detailed error message is set in spcprm::err if enabled, see wcserr_enable().

spcx2s()

Transform to spectral coordinates.

spcx2s() transforms intermediate world coordinates to spectral coordinates.

in,out	spc	Spectral transformation parameters.
in	nx	Vector length.
in	SX	Vector stride.
in	sspec	Vector stride.
in	X	Intermediate world coordinates, in SI units.

out	spec	Spectral coordinates, in SI units.
out	stat	Status return value status for each vector element:
		0: Success.1: Invalid value of x.

Returns

Status return value:

- 0: Success.
- 1: Null spcprm pointer passed.
- 2: Invalid spectral parameters.
- 3: One or more of the x coordinates were invalid, as indicated by the stat vector.

For returns > 1, a detailed error message is set in spcprm::err if enabled, see wcserr_enable().

spcs2x()

Transform spectral coordinates.

spcs2x() transforms spectral world coordinates to intermediate world coordinates.

spc	Spectral transformation parameters.
nspec	Vector length.
sspec	Vector stride.
SX	Vector stride.
spec	Spectral coordinates, in SI units.
X	Intermediate world coordinates, in SI units.
stat	Status return value status for each vector element: • 0: Success. • 1: Invalid value of spec.
	nspec sspec sx spec x

Returns

Status return value:

- · 0: Success.
- 1: Null spcprm pointer passed.
- 2: Invalid spectral parameters.
- 4: One or more of the spec coordinates were invalid, as indicated by the stat vector.

For returns > 1, a detailed error message is set in spcprm::err if enabled, see wcserr_enable().

spctype()

Spectral CTYPEia keyword analysis.

spctype() checks whether a **CTYPE**ia keyvalue is a valid spectral axis type and if so returns information derived from it relating to the associated S-, P-, and X-type spectral variables (see explanation above).

The return arguments are guaranteed not be modified if CTYPEia is not a valid spectral type; zero-pointers may be specified for any that are not of interest.

A deprecated form of this function, spctyp(), lacks the wcserr** parameter.

in	ctype	The CTYPEia keyvalue, (eight characters with null termination).
out	stype	The four-letter name of the S -type spectral variable copied or translated from ctype. If a non-zero pointer is given, the array must accommodate a null- terminated string of length 5.
out	scode	The three-letter spectral algorithm code copied or translated from ctype. Logarithmic ('LOG') and tabular ('TAB') codes are also recognized. If a non-zero pointer is given, the array must accommodate a null-terminated string of length 4.
out	sname	Descriptive name of the S -type spectral variable. If a non-zero pointer is given, the array must accomodate a null-terminated string of length 22.
out	units	SI units of the S -type spectral variable. If a non-zero pointer is given, the array must accomodate a null-terminated string of length 8.
out	ptype	Character code for the P -type spectral variable derived from ctype, one of 'F', 'W', 'A', or 'V'.
out	xtype	Character code for the X -type spectral variable derived from ctype, one of 'F', 'W', 'A', or 'V'. Also, 'w' and 'a' are synonymous to 'W' and 'A' for grisms in vacuo and air respectively. Set to 'L' or 'T' for logarithmic (' LOG ') and tabular (' TAB ') axes.

out	restreq	Multivalued flag that indicates whether rest frequency or wavelength is required to compute spectral variables for this CTYPEia:
		0: Not required.
		• 1: Required for the conversion between S - and P -types (e.g. 'ZOPT-F2W').
		• 2: Required for the conversion between P - and X -types (e.g. 'BETA-W2V').
		 3: Required for the conversion between S- and P-types, and between P- and X-types, but not between S- and X-types (this applies only for 'VRAD-V2F', 'VOPT-V2W', and 'ZOPT-V2W').
		Thus the rest frequency or wavelength is required for spectral coordinate computations (i.e. between S - and X -types) only if ${}^{\text{restreq\$3}} \stackrel{!=\ 0}{}$
out	err	If enabled, for function return values > 1, this struct will contain a detailed error message, see wcserr_enable(). May be NULL if an error message is not desired. Otherwise, the user is responsible for deleting the memory allocated for the wcserr struct.

Returns

Status return value:

- 0: Success.
- 2: Invalid spectral parameters (not a spectral CTYPEia).

spcspxe()

Spectral keyword analysis.

spcspxe() analyses the CTYPEia and CRVALia FITS spectral axis keyword values and returns information about the associated X-type spectral variable.

A deprecated form of this function, spcspx(), lacks the wcserr** parameter.

in	ctypeS	Spectral axis type, i.e. the CTYPEia keyvalue, (eight characters with null
		termination). For non-grism axes, the character code for the P -type spectral variable
		in the algorithm code (i.e. the eighth character of CTYPEia) may be set to '?' (it will
		not be reset).

in	crvalS	Value of the S -type spectral variable at the reference point, i.e. the ${\tt CRVAL}ia$ keyvalue, SI units.
in	restfrq,restwav	Rest frequency [Hz] and rest wavelength in vacuo [m], only one of which need be given, the other should be set to zero.
out	ptype	Character code for the P -type spectral variable derived from ctypeS, one of 'F', 'W', 'A', or 'V'.
out	xtype	Character code for the X -type spectral variable derived from ctypeS, one of 'F', 'W', 'A', or 'V'. Also, 'w' and 'a' are synonymous to 'W' and 'A' for grisms in vacuo and air respectively; crvalX and dXdS (see below) will conform to these.
out	restreq	Multivalued flag that indicates whether rest frequency or wavelength is required to compute spectral variables for this CTYPEia, as for spctype().
out	crvalX	Value of the X -type spectral variable at the reference point, SI units.
out	dXdS	The derivative, dX/dS , evaluated at the reference point, SI units. Multiply the CDELTia keyvalue by this to get the pixel spacing in the X -type spectral coordinate.
out	err	If enabled, for function return values > 1, this struct will contain a detailed error message, see wcserr_enable(). May be NULL if an error message is not desired. Otherwise, the user is responsible for deleting the memory allocated for the wcserr struct.

Returns

Status return value:

- 0: Success.
- 2: Invalid spectral parameters.

spcxpse()

Spectral keyword synthesis.

spcxpse(), for the spectral axis type specified and the value provided for the X-type spectral variable at the reference point, deduces the value of the FITS spectral axis keyword **CRVAL**ia and also the derivative dS/dX which may be used to compute **CDELT**ia. See above for an explanation of the S-, P-, and X-type spectral variables.

A deprecated form of this function, spcxps(), lacks the wcserr** parameter.

in	ctypeS	The required spectral axis type, i.e. the CTYPEia keyvalue, (eight characters with null termination). For non-grism axes, the character code for the P -type spectral variable in the algorithm code (i.e. the eighth character of CTYPEia) may be set to '?' (it will not be reset).
in	crvalX	Value of the X -type spectral variable at the reference point (N.B. NOT the CRVALia keyvalue), SI units.
in	restfrq,restwav	Rest frequency [Hz] and rest wavelength in vacuo [m], only one of which need be given, the other should be set to zero.
out	ptype	Character code for the P -type spectral variable derived from ctypeS, one of 'F', 'W', 'A', or 'V'.
out	xtype	Character code for the X -type spectral variable derived from ctypeS, one of 'F', 'W', 'A', or 'V'. Also, 'w' and 'a' are synonymous to 'W' and 'A' for grisms; crvalX and cdeltX must conform to these.
out	restreq	Multivalued flag that indicates whether rest frequency or wavelength is required to compute spectral variables for this CTYPEia, as for spctype().
out	crvalS	Value of the S -type spectral variable at the reference point (i.e. the appropriate ${\tt CRVAL}$ ia keyvalue), SI units.
out	dSdX	The derivative, dS/dX , evaluated at the reference point, SI units. Multiply this by the pixel spacing in the X -type spectral coordinate to get the CDELTia keyvalue.
out	err	If enabled, for function return values > 1, this struct will contain a detailed error message, see wcserr_enable(). May be NULL if an error message is not desired. Otherwise, the user is responsible for deleting the memory allocated for the wcserr struct.

Returns

Status return value:

- 0: Success.
- 2: Invalid spectral parameters.

spctrne()

Spectral keyword translation.

spctrne() translates a set of FITS spectral axis keywords into the corresponding set for the specified spectral axis type. For example, a 'FREQ' axis may be translated into 'ZOPT-F2W' and vice versa.

A deprecated form of this function, spctrn(), lacks the wcserr** parameter.

in	ctypeS1	Spectral axis type, i.e. the CTYPE ia keyvalue, (eight characters with null termination). For non-grism axes, the character code for the <i>P</i> -type spectral variable in the algorithm code (i.e. the eighth character of CTYPE ia) may be set to '?' (it will not be reset).
in	crvalS1	Value of the S -type spectral variable at the reference point, i.e. the ${\tt CRVALia}$ keyvalue, SI units.
in	cdeltS1	Increment of the S -type spectral variable at the reference point, SI units.
in	restfrq,restwav	Rest frequency [Hz] and rest wavelength in vacuo [m], only one of which need be given, the other should be set to zero. Neither are required if the translation is between wave-characteristic types, or between velocity-characteristic types. E.g., required for 'FREQ' -> 'ZOPT-F2W', but not required for 'VELO-F2V' -> 'ZOPT-F2W'.
in,out	ctypeS2	Required spectral axis type (eight characters with null termination). The first four characters are required to be given and are never modified. The remaining four, the algorithm code, are completely determined by, and must be consistent with, ctypeS1 and the first four characters of ctypeS2. A non-zero status value will be returned if they are inconsistent (see below). However, if the final three characters are specified as "???", or if just the eighth character is specified as '?', the correct algorithm code will be substituted (applies for grism axes as well as non-grism).
out	crvalS2	Value of the new S -type spectral variable at the reference point, i.e. the new ${\tt CRVAL}$ ia keyvalue, ${\tt SI}$ units.
out	cdeltS2	Increment of the new S -type spectral variable at the reference point, i.e. the new CDELTia keyvalue, SI units.
out	err	If enabled, for function return values > 1, this struct will contain a detailed error message, see wcserr_enable(). May be NULL if an error message is not desired. Otherwise, the user is responsible for deleting the memory allocated for the wcserr struct.

Returns

Status return value:

- 0: Success.
- 2: Invalid spectral parameters.

A status value of 2 will be returned if restfrq or restwav are not specified when required, or if ctypeS1 or ctypeS2 are self-inconsistent, or have different spectral X-type variables.

spcaips()

Translate AIPS-convention spectral keywords.

spcaips() translates AIPS-convention spectral CTYPEia and VELREF keyvalues.

in	ctypeA	CTYPEia keyvalue possibly containing an AIPS-convention spectral code (eight characters, need not be null-terminated).
in	velref	AIPS-convention VELREF code. It has the following integer values:
111	vener	1: LSR kinematic, originally described simply as "LSR" without distinction between the kinematic and dynamic definitions.
		2: Barycentric, originally described as "HEL" meaning heliocentric.
		 3: Topocentric, originally described as "OBS" meaning geocentric but widely interpreted as topocentric.
		AIPS++ extensions to VELREF are also recognized:
		• 4: LSR dynamic.
		• 5: Geocentric.
		6: Source rest frame.
		7: Galactocentric.
		For an AIPS 'VELO' axis, a radio convention velocity (VRAD) is denoted by adding 256 to VELREF, otherwise an optical velocity (VOPT) is indicated (this is not applicable to 'FREQ' or 'FELO' axes). Setting velref to 0 or 256 chooses between optical and radio velocity without specifying a Doppler frame, provided that a frame is encoded in ctypeA. If not, i.e. for ctypeA = 'VELO', ctype will be returned as 'VELO'. VELREF takes precedence over CTYPEia in defining the Doppler frame, e.g. ctypeA = 'VELO-HEL' velref = 1
		returns ctype = 'VOPT' with specsys set to 'LSRK'. If omitted from the header, the default value of VELREF is 0.
out	ctype	Translated CTYPEia keyvalue, or a copy of ctypeA if no translation was performed (in which case any trailing blanks in ctypeA will be replaced with nulls).
out	specsys	Doppler reference frame indicated by VELREF or else by CTYPE ia with value corresponding to the SPECSYS keyvalue in the FITS WCS standard. May be returned blank if neither specifies a Doppler frame, e.g. ctypeA = ' FELO ' and velref%256 == 0.

Returns

Status return value:

- -1: No translation required (not an error).
- 0: Success.
- 2: Invalid value of **VELREF**.

spctyp()

spcspx()

spcxps()

spctrn()

6.15.5 Variable Documentation

spc_errmsg

```
const char * spc_errmsg[] [extern]
```

Status return messages.

Error messages to match the status value returned from each function.

00023 *====
00024 *
00025 \star WCSLIB 8.3 - C routines that implement the FITS World Coordinate System
00026 \star (WCS) standard. Refer to the README file provided with WCSLIB for an
00027 * overview of the library.
00028 *
00029
00030 * Summary of the spc routines
00031 *
00032 \star Routines in this suite implement the part of the FITS World Coordinate
00033 * System (WCS) standard that deals with spectral coordinates, as described in
00034 *
00035 =
          "Representations of world coordinates in FITS",
          Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061 (WCS Paper I)
00036 =
00037 =
00038 =
          "Representations of spectral coordinates in FITS",
          Greisen, E.W., Calabretta, M.R., Valdes, F.G., & Allen, S.L.
00039 =
00040 =
          2006, A&A, 446, 747 (WCS Paper III)
00041 *
00042 \star These routines define methods to be used for computing spectral world
00043 \star coordinates from intermediate world coordinates (a linear transformation
00044 * of image pixel coordinates), and vice versa. They are based on the spoprm
00045 * struct which contains all information needed for the computations.
00046 * struct contains some members that must be set by the user, and others that
00047 \star are maintained by these routines, somewhat like a C++ class but with no
00048 \star encapsulation.
00049 *
00050 \star Routine spcini() is provided to initialize the spcprm struct with default
00051 \star values, spcfree() reclaims any memory that may have been allocated to store 00052 \star an error message, spcsize() computes its total size including allocated
00053 \star memory, spceng() returns information about the state of the struct, and
00054 \star spcprt() prints its contents.
00055
00056 \star spcperr() prints the error message(s) (if any) stored in a spcprm struct.
00057 *
00058 \star A setup routine, spcset(), computes intermediate values in the spcprm struct
00059 \star from parameters in it that were supplied by the user. The struct always
00060 \star needs to be set up by spcset() but it need not be called explicitly - refer
00061 \star to the explanation of spcprm::flag.
00062
00063 \star spcx2s() and spcs2x() implement the WCS spectral coordinate transformations.
00064 * In fact, they are high level driver routines for the lower level spectral
00065 * coordinate transformation routines described in spx.h.
00066 *
00067 \star A number of routines are provided to aid in analysing or synthesising sets
00068 * of FITS spectral axis keywords:
00069 *
00070 *
           - spctype() checks a spectral CTYPEia keyword for validity and returns
00071 *
            information derived from it.
00072 *
00073 *
          - Spectral keyword analysis routine spcspxe() computes the values of the
00074 *
           X-type spectral variables for the S-type variables supplied.
00075 *
00076 *
          - Spectral keyword synthesis routine, spcxpse(), computes the S-type
00077 *
            variables for the X-types supplied.
00078 *
00079 *
          - Given a set of spectral keywords, a translation routine, \operatorname{spctrne}\left(\right) ,
00080 *
            produces the corresponding set for the specified spectral CTYPEia.
00081 *
00082 *
          - spcaips() translates AIPS-convention spectral CTYPEia and VELREF
00083 *
            keyvalues.
```

```
00084 *
00085 \star Spectral variable types - S, P, and X:
00086 *
00087 * A few words of explanation are necessary regarding spectral variable types
00088 * in FITS.
00089
00090 \star Every FITS spectral axis has three associated spectral variables:
00091 *
00092 *
            S-type: the spectral variable in which coordinates are to be
              expressed. Each S-type is encoded as four characters and is linearly related to one of four basic types as follows:
00093 *
00094 *
00095 *
00096 *
              F (Frequency):
00097 *
                - 'FREQ': frequency
                - 'AFRQ': angular frequ
- 'ENER': photon energy
00098 *
                             angular frequency
00099 *
                - 'WAVN': wave number
00100 *
                 - 'VRAD': radio velocity
00101 *
00103 *
              W (Wavelength in vacuo):
                - 'WAVE': wavelength
- 'VOPT': optical velocity
- 'ZOPT': redshift
00104 *
00105 *
00106 *
00107 *
00108 *
              A (wavelength in Air):
                   'AWAV': wavelength in air
00109 *
00110 *
              V (Velocity):
  - 'VELO': relativistic velocity
  - 'BETA': relativistic beta factor
00111 *
00112 *
00113 *
00114 *
00115 *
              The S-type forms the first four characters of the CTYPEia keyvalue,
00116 *
              and CRVALia and CDELTia are expressed as S-type quantities so that
00117 *
              they provide a first-order approximation to the S-type variable at
00118 *
              the reference point.
00119 *
00120 *
              Note that 'AFRO', angular frequency, is additional to the variables
              defined in WCS Paper III.
00122 *
00123 *
            P-type: the basic spectral variable (F, W, A, or V) with which the
00124 *
              S-type variable is associated (see list above).
00125 *
00126 *
              For non-grism axes, the P-type is encoded as the eighth character of
00127 *
              CTYPEia.
00128 *
00129 *
            X-type: the basic spectral variable (F, W, A, or V) for which the
00130 *
              spectral axis is linear, grisms excluded (see below).
00131 *
00132 *
              For non-grism axes, the X-type is encoded as the sixth character of
00133 *
              CTYPEia.
00134 *
00135 *
            Grisms: Grism axes have normal S-, and P-types but the axis is linear,
00136 *
              not in any spectral variable, but in a special "grism parameter"
              The X-type spectral variable is either W or A for grisms in vacuo or air respectively, but is encoded as 'w' or 'a' to indicate that an
00137 *
00138 *
              additional transformation is required to convert to or from the
00139 *
              grism parameter. The spectral algorithm code for grisms also has a
00141 *
              special encoding in CTYPEia, either 'GRI' (in vacuo) or 'GRA' (in air).
00142 *
00143 * In the algorithm chain, the non-linear transformation occurs between the
00144 \star X-type and the P-type variables; the transformation between P-type and
00145 \star S-type variables is always linear.
00147 \star When the P-type and X-type variables are the same, the spectral axis is
00148 \star linear in the S-type variable and the second four characters of CTYPEia
00149 \star are blank. This can never happen for grism axes.
00150 *
00151 \star As an example, correlating radio spectrometers always produce spectra that
00151 * As an example, Correlating radio spectrometers always produce spectra that 00152 * are regularly gridded in frequency; a redshift scale on such a spectrum is 00153 * non-linear. The required value of CTYPEia would be 'ZOPT-F2W', where the 00154 * desired S-type is 'ZOPT' (redshift), the P-type is necessarily 'W' 00155 * (wavelength), and the X-type is 'F' (frequency) by the nature of the
00156 * instrument.
00157 *
00158 * Air-to-vacuum wavelength conversion:
00160 * Please refer to the prologue of spx.h for important comments relating to the
00161 * air-to-vacuum wavelength conversion.
00162 *
00163 * Argument checking:
00164 *
00165 \star The input spectral values are only checked for values that would result in
00166 * floating point exceptions. In particular, negative frequencies and
00167 \star wavelengths are allowed, as are velocities greater than the speed of
00168 \star light. The same is true for the spectral parameters - rest frequency and
00169 * wavelength.
00170 *
```

```
00171 * Accuracy:
00172 *
00173 \star No warranty is given for the accuracy of these routines (refer to the
00174 \star copyright notice); intending users must satisfy for themselves their
00175 \star adequacy for the intended purpose. However, closure effectively to within
00176 * double precision rounding error was demonstrated by test routine tspc.c
00177 * which accompanies this software.
00178 *
00179 *
00180 \star spcini() - Default constructor for the spcprm struct
00181 * --
00182 * spcini() sets all members of a spcprm struct to default values. It should
00183 * be used to initialize every spcprm struct.
00184 *
00185 \star PLEASE NOTE: If the spcprm struct has already been initialized, then before
00186 \star reinitializing, it spcfree() should be used to free any memory that may have 00187 \star been allocated to store an error message. A memory leak may otherwise
00188 * result.
00189 *
00190 * Given and returned:
00191 * spc
                    struct spcprm*
00192 *
                                Spectral transformation parameters.
00193 *
00194 * Function return value:
00195 *
                               Status return value:
                    int
00196 *
                                 0: Success.
00197 *
                                  1: Null spcprm pointer passed.
00198 *
00199 *
00200 \star spcfree() - Destructor for the spcprm struct
00201 *
00202 \star spcfree() frees any memory that may have been allocated to store an error
00203 * message in the spcprm struct.
00204 *
00205 * Given:
00206 *
          spc
                     struct spcprm*
00207 *
                               Spectral transformation parameters.
00209 * Function return value:
00210 *
                               Status return value:
                    int
00211 *
                                  0: Success.
00212 *
                                  1: Null spcprm pointer passed.
00213 *
00214 *
00215 \star spcsize() - Compute the size of a spcprm struct
00216 *
00217 \star spcsize() computes the full size of a spcprm struct, including allocated
00218 * memory.
00219 *
00220 * Given:
00221 * spc
                    const struct spcprm*
00222 *
                               Spectral transformation parameters.
00223 *
00224 *
                               If NULL, the base size of the struct and the allocated
00225 *
                               size are both set to zero.
00226 *
00227 * Returned:
00228 *
                     int[2]
                               The first element is the base size of the struct as
                                returned by sizeof(struct spcprm). The second element
00229 *
00230 *
                                is the total allocated size, in bytes. This figure
00231 *
                                includes memory allocated for the constituent struct,
00232 *
                               spcprm::err.
00233 *
00234 *
                               It is not an error for the struct not to have been set
00235 *
                               up via spcset().
00236 *
00237 * Function return value:
00238 *
                    int
                               Status return value:
00239 *
                                 0: Success.
00240 *
00241 *
00242 \star spcenq() - enquire about the state of a spcprm struct
00243 *
00244 \star spcenq() may be used to obtain information about the state of a spcprm
00245 * struct. The function returns a true/false answer for the enquiry asked.
00246 *
00247 * Given:
00248 * spc
                   const struct spcprm*
00249 *
                                Spectral transformation parameters.
00250 *
00251 *
                               Enquiry according to the following parameters:
          enquiry int
                                 SPCENO_MEM: memory in the struct is being managed by WCSLIB (see spcini()).
00252 *
00253 *
00254 *
                                  SPCENQ_SET: the struct has been set up by spcset().
00255 *
                                  SPCENQ_BYP: the struct is in bypass mode (see
00256 *
                                              spcset()).
                                These may be combined by logical OR, e.g.
00257 *
```

```
00258 *
                                 SPCENQ_MEM | SPCENQ_SET. The enquiry result will be
00259 *
                                 the logical AND of the individual results.
00260 *
00261 * Function return value:
                                 Enquiry result:
00262 *
                     int
00263 *
                                   0: No.
00264 *
00265 *
00266 *
00267 \star spcprt() - Print routine for the spcprm struct
00268 * -
00269 \star spcprt() prints the contents of a spcprm struct using wcsprintf(). Mainly
00270 * intended for diagnostic purposes.
00271 *
00272 * Given:
00273 * spc
                     const struct spcprm*
00274 *
                                 Spectral transformation parameters.
00275 *
00276 * Function return value:
00277 *
                                 Status return value:
                     int
00278 *
                                    0: Success.
00279 *
                                    1: Null spcprm pointer passed.
00280 *
00281 *
00282 * spcperr() - Print error messages from a spcprm struct
00284 \star spcperr() prints the error message(s) (if any) stored in a spcprm struct.
00285 \star If there are no errors then nothing is printed. It uses wcserr_prt(), q.v.
00286 *
00287 * Given:
00288 * spc
                    const struct spcprm*
00289 *
                                 Spectral transformation parameters.
00290 *
00291 *
          prefix
                      const char *
                                 If non-NULL, each output line will be prefixed with
00292 *
00293 *
                                 this string.
00294 *
00295 * Function return value:
00296 *
                     int
                               Status return value:
00297 *
                                  0: Success.
00298 *
                                    1: Null spcprm pointer passed.
00299 *
00300 *
00301 * spcset() - Setup routine for the spcprm struct
00302 *
00303 \star spcset() sets up a spcprm struct according to information supplied within
00304 * it.
00305 *
00306 * Note that this routine need not be called directly; it will be invoked by
00307 * spcx2s() and spcs2x() if spcprm::flag is anything other than a predefined
00308 * magic value.
00309 *
00310 \star spcset() normally operates regardless of the value of spcprm::flag; i.e.
00311 * even if a struct was previously set up it will be reset unconditionally.
00312 * However, a speprm struct may be put into "bypass" mode by invoking speset()
00313 * initially with speprm::flag == 1 (rather than 0). speset() will return
00314 * immediately if invoked on a struct in that state. To take a struct out of
00315 * bypass mode, simply reset spcprm::flag to zero. See also spcenq().
00316 *
00317 \star Given and returned:
00318 * spc
                   struct spcprm*
00319 *
                                 Spectral transformation parameters.
00320 *
00321 * Function return value:
00322 *
                                 Status return value:
                      int
00323 *
                                    0: Success.
00324 *
                                    1: Null spcprm pointer passed.
00325 *
                                    2: Invalid spectral parameters.
00326 *
00327
                                 For returns > 1, a detailed error message is set in
00328 *
                                 spcprm::err if enabled, see wcserr_enable().
00329 *
00330
00331 * spcx2s() - Transform to spectral coordinates
00332 *
00333 \star spcx2s() transforms intermediate world coordinates to spectral coordinates.
00334 *
00335 * Given and returned:
00336 * spc
                     struct spcprm*
00337 *
                                 Spectral transformation parameters.
00338 *
00339 * Given:
00340 *
                      int
                                 Vector length.
00341 *
00342 *
          sx
                      int
                                 Vector stride.
00343 *
00344 * sspec
                      int
                                 Vector stride.
```

```
00345 *
00346 *
                    const double[]
00347 *
                               Intermediate world coordinates, in SI units.
00348 *
00349 * Returned:
00350 *
                    double[] Spectral coordinates, in SI units.
          spec
00351 *
00352 *
                              Status return value status for each vector element:
                                0: Success.
00353 *
00354 *
                                 1: Invalid value of x.
00355 *
00356 * Function return value:
00357 *
                               Status return value:
                    int
                                 0: Success.
00358 *
00359 *
                                 1: Null spcprm pointer passed.
00360 *
                                 2: Invalid spectral parameters.
00361 *
                                 3: One or more of the x coordinates were invalid.
00362 *
                                    as indicated by the stat vector.
00363 *
00364 *
                               For returns > 1, a detailed error message is set in
00365 *
                               spcprm::err if enabled, see wcserr_enable().
00366 *
00367
00368 * spcs2x() - Transform spectral coordinates
00369 *
00370 * spcs2x() transforms spectral world coordinates to intermediate world
00371 * coordinates.
00372 *
00373 \star Given and returned:
00374 *
         spc
                    struct spcprm*
00375 *
                               Spectral transformation parameters.
00376 *
00377 * Given:
00378 *
                    int
                              Vector length.

                                 2: Invalid spectral parameters.
00399 *
                                 4: One or more of the spec coordinates were
00400 *
                                    invalid, as indicated by the stat vector.
00401 *
00402 *
                               For returns > 1, a detailed error message is set in
00403 *
                               spcprm::err if enabled, see wcserr_enable().
00404 *
00405 *
00406 * spctype() - Spectral CTYPEia keyword analysis
00407 *
00408 * spctype() checks whether a CTYPEia keyvalue is a valid spectral axis type
00409 \star and if so returns information derived from it relating to the associated S-,
00410 \star P-, and X-type spectral variables (see explanation above).
00411 *
00412 \star The return arguments are guaranteed not be modified if CTYPEia is not a
00413 * valid spectral type; zero-pointers may be specified for any that are not of
00414 * interest.
00415
00416 \star A deprecated form of this function, spctyp(), lacks the wcserr\star\star parameter.
00417 *
00418 * Given:
00419 *
         ctype
                    const char[9]
00420 *
                               The CTYPEia keyvalue, (eight characters with null
00421 *
                               termination).
00422 *
00423 * Returned:
                               The four-letter name of the S-type spectral variable
00424 *
         stype
                    char[]
                               copied or translated from ctype. If a non-zero
00425 *
00426 *
                               pointer is given, the array must accomodate a null-
00427 *
                               terminated string of length 5.
00428 *

                                 struct will contain a detailed error message, see
00661 *
                                 wcserr_enable(). May be NULL if an error message is
                                 not desired. Otherwise, the user is responsible for
00662 *
                                 deleting the memory allocated for the wcserr struct.
00663 *
00664 *
00665 * Function return value:
                                 Status return value:
00666 *
                     int
00667 *
                                   0: Success.
00668 *
                                   2: Invalid spectral parameters.
00669 *
00670 *
                                 A status value of 2 will be returned if restfrq or
00671 *
                                 \verb"restwav" are not specified when required, or if ctypeS1"
00672 *
                                 or ctypeS2 are self-inconsistent, or have different
00673 *
                                 spectral X-type variables.
00674 *
00676 * spcaips() - Translate AIPS-convention spectral keywords
00677 *
00678 \star spcaips() translates AIPS-convention spectral CTYPEia and VELREF keyvalues.
00679 *
00680 * Given:
00681 *
          ctypeA
                     const char[9]
00682 *
                                 CTYPEia keyvalue possibly containing an
00683 *
                                 AIPS-convention spectral code (eight characters, need
00684 *
                                 not be null-terminated).
00685 *
                                 AIPS-convention VELREF code. It has the following
00686 *
          velref
                    int
00687 *
                                 integer values:
00688 *
                                   1: LSR kinematic, originally described simply as
00689 *
                                       "LSR" without distinction between the kinematic
00690 *
                                       and dynamic definitions.
                                   2: Barycentric, originally described as "HEL"
meaning heliocentric.
00691 *
00692 *
```

```
3: Topocentric, originally described as "OBS"
00694 *
                                       meaning geocentric but widely interpreted as
00695 *
                                       topocentric.
00696 *
                                 AIPS++ extensions to VELREF are also recognized:
00697 *
                                    4: LSR dynamic.
00698 *
                                    5: Geocentric.
00699
                                    6: Source rest frame.
00700 *
                                    7: Galactocentric.
00701 *
                                 For an AIPS 'VELO' axis, a radio convention velocity (VRAD) is denoted by adding 256 to VELREF, otherwise an optical velocity (VOPT) is indicated (this is not applicable to 'FREQ' or 'FELO' axes). Setting velref
00702 *
00703 *
00704 *
00705 *
00706 *
                                  to 0 or 256 chooses between optical and radio velocity
00707 *
                                  without specifying a Doppler frame, provided that a
                                 frame is encoded in ctypeA. If not, i.e. for ctypeA = 'VELO', ctype will be returned as 'VELO'.
00708 *
00709 *
00710 *
00711 *
                                 VELREF takes precedence over CTYPEia in defining the
00712 *
                                 Doppler frame, e.g.
00713 *
                                    ctypeA = 'VELO-HEL'
00714 =
00715 =
                                   velref = 1
00716 *
00717 *
                                 returns ctype = 'VOPT' with specsys set to 'LSRK'.
00718
00719 *
                                 If omitted from the header, the default value of
                                 VELREF is 0.
00720 *
00721 *
00722 * Returned:
00723 *
                               Translated CTYPEia keyvalue, or a copy of ctypeA if no
                      char[9]
          ctype
00724 *
                                 translation was performed (in which case any trailing
00725 *
                                 blanks in ctypeA will be replaced with nulls).
00726 *
00727 *
                    char[9]
                                 Doppler reference frame indicated by VELREF or else
          specsys
00728 *
                                 by CTYPEia with value corresponding to the SPECSYS keyvalue in the FITS WCS standard. May be returned
00729 *
00730 *
                                 blank if neither specifies a Doppler frame, e.g.
00731 *
                                 ctypeA = 'FELO' and velref%256 == 0.
00732 *
00733 * Function return value:
00734 *
                     int.
                                 Status return value:
00735 *
                                  -1: No translation required (not an error).
00736 *
                                    0: Success.
00737 *
                                    2: Invalid value of VELREF.
00738 *
00739 *
00740 \star spcprm struct - Spectral transformation parameters
00741 *
00742 * The spcprm struct contains information required to transform spectral
00743 \star coordinates. It consists of certain members that must be set by the user
00744 * ("given") and others that are set by the WCSLIB routines ("returned").
00745 \star of the latter are supplied for informational purposes while others are for
00746 \star internal use only.
00747 *
00748 *
           int flag
00749 *
             (Given and returned) This flag must be set to zero (or 1, see spcset())
00750 *
             whenever any of the following spcprm members are set or changed:
00751 *
00752 *
               - spcprm::type,
00753 *
               - spcprm::code,
00754 *
               - spcprm::crval,
00755 *
               - spcprm::restfrq,
00756 *
               - spcprm::restwav,
00757 *
               - spcprm::pv[].
00758 *
00759 *
             This signals the initialization routine, spcset(), to recompute the
00760 *
             returned members of the spcprm struct. spcset() will reset flag to
00761 *
             indicate that this has been done.
00762 *
00763 *
          char type[8]
            (Given) Four-letter spectral variable type, e.g "ZOPT" for CTYPEia = 'ZOPT-F2W'. (Declared as char[8] for alignment reasons.)
00764 *
00765 *
00766 *
00767 *
          char code[4]
00768 *
             (Given) Three-letter spectral algorithm code, e.g "F2W" for
00769 *
             CTYPEia = 'ZOPT-F2W'.
00770 *
00771 *
          double crval
00772 *
             (Given) Reference value (CRVALia), SI units.
00773 *
00774 *
          double restfrq
00775 *
             (Given) The rest frequency [Hz], and ...
00776 *
00777 *
          double restwav
00778 *
             (Given) \dots the rest wavelength in vacuo [m], only one of which need be
00779 *
            given, the other should be set to zero. Neither are required if the
```

```
X and S spectral variables are both wave-characteristic, or both
00781 *
            velocity-characteristic, types.
00782 *
00783 *
          double pv[7]
            (Given) Grism parameters for 'GRI' and 'GRA' algorithm codes:
00784 *
              - 0: G, grating ruling density.
- 1: m, interference order.
00785 *
00787 *
              - 2: alpha, angle of incidence [deg].
00788 *
              - 3: n_r, refractive index at the reference wavelength, lambda_r.
00789 *
              - 4: n'_r, dn/dlambda at the reference wavelength, lambda_r (/m).
              - 5: epsilon, grating tilt angle [deg].
- 6: theta, detector tilt angle [deg].
00790 *
00791 *
00792 *
00793 \star The remaining members of the spcprm struct are maintained by spcset() and
00794 * must not be modified elsewhere:
00795 *
00796 *
          double w[6]
00797 *
            (Returned) Intermediate values:
              - 0: Rest frequency or wavelength (SI).
00799 *
              - 1: The value of the X-type spectral variable at the reference point
00800 *
                 (SI units).
              - 2: dX/dS at the reference point (SI units).
00801 *
00802 *
             The remainder are grism intermediates.
00803 *
00804 *
          int isGrism
           (Returned) Grism coordinates?
00805 *
00806 *
              - 0: no,
              - 1: in vacuum,
00807 *
              - 2: in air.
00808 *
00809 *
00810 *
          int padding1
00811 *
             (An unused variable inserted for alignment purposes only.)
00812 *
00813 *
00814 *
             (Returned) If enabled, when an error status is returned, this struct
            contains detailed information about the error, see wcserr_enable().
00815 *
00816 *
          void *padding2
00818 *
            (An unused variable inserted for alignment purposes only.)
00819 *
          int (*spxX2P)(SPX_ARGS)
00820 *
            (Returned) The first and ...
          int (*spxP2S)(SPX_ARGS)
00821 *
00822 *
            (Returned) ... the second of the pointers to the transformation
00823 *
            functions in the two-step algorithm chain X \rightarrow P \rightarrow S in the
            pixel-to-spectral direction where the non-linear transformation is from
00824 *
00825 *
             X to P. The argument list, SPX_ARGS, is defined in spx.h.
00826 *
00827 *
          int (*spxS2P)(SPX_ARGS)
00828 *
            (Returned) The first and ...
00829 *
          int (*spxP2X)(SPX_ARGS)
            (Returned) ... the second of the pointers to the transformation
00831 *
             functions in the two-step algorithm chain S \rightarrow P \rightarrow X in the
00832 *
             spectral-to-pixel direction where the non-linear transformation is from
00833 *
            P to X. The argument list, SPX_ARGS, is defined in spx.h.
00834 *
00835 *
00836 * Global variable: const char *spc_errmsg[] - Status return messages
00837 *
00838 \star Error messages to match the status value returned from each function.
00839 *
00840 *==

6.17 sph.h File Reference

Functions

• int sphx2s (const double eul[5], int nphi, int ntheta, int spt, int sxy, const double phi[], const double theta[], double lng[], double lat[])

Rotation in the pixel-to-world direction.

• int sphs2x (const double eul[5], int nlng, int nlat, int sll, int spt, const double lng[], const double lat[], double phi[], double theta[])

Rotation in the world-to-pixel direction.

int sphdpa (int nfield, double lng0, double lat0, const double lng[], const double lat[], double dist[], double pa[])

Compute angular distance and position angle.

• int sphpad (int nfield, double lng0, double lat0, const double dist[], const double pa[], double lng[], double lat[])

Compute field points offset from a given point.

6.17.1 Detailed Description

Routines in this suite implement the spherical coordinate transformations defined by the FITS World Coordinate System (WCS) standard

```
"Representations of world coordinates in FITS",
Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061 (WCS Paper I)
"Representations of celestial coordinates in FITS",
Calabretta, M.R., & Greisen, E.W. 2002, A&A, 395, 1077 (WCS Paper II)
```

The transformations are implemented via separate functions, sphx2s() and sphs2x(), for the spherical rotation in each direction.

A utility function, sphdpa(), computes the angular distances and position angles from a given point on the sky to a number of other points. sphpad() does the complementary operation - computes the coordinates of points offset by the given angular distances and position angles from a given point on the sky.

6.17.2 Function Documentation

sphx2s()

Rotation in the pixel-to-world direction.

sphx2s() transforms native coordinates of a projection to celestial coordinates.

Parameters

in	eul	Euler angles for the transformation:	
		0: Celestial longitude of the native pole [deg].	
		 1: Celestial colatitude of the native pole, or native colatitude of the celestial pole [deg]. 	
		2: Native longitude of the celestial pole [deg].	
		• 3: cos(eul[1])	
		• 4: $sin(eul[1])$	
in	nphi,ntheta	Vector lengths.	
in	spt,sxy	Vector strides.	
in	phi,theta	Longitude and latitude in the native coordinate system of the projection [deg].	
out	Ing,lat	Celestial longitude and latitude [deg]. These may refer to the same storage as <i>phi</i> and <i>theta</i> respectively.	

Returns

Status return value:

• 0: Success.

sphs2x()

```
const double lat[],
double phi[],
double theta[] )
```

Rotation in the world-to-pixel direction.

sphs2x() transforms celestial coordinates to the native coordinates of a projection.

Parameters 4 8 1

in	eul	Euler angles for the transformation:	
		0: Celestial longitude of the native pole [deg].	
		 1: Celestial colatitude of the native pole, or native colatitude of the celestial pole [deg]. 	
		2: Native longitude of the celestial pole [deg].	
		• 3: cos(eul[1])	
		• 4: $sin(eul[1])$	
in	nlng,nlat	Vector lengths.	
in	sll,spt	Vector strides.	
in	Ing,lat	Celestial longitude and latitude [deg].	
out	phi,theta	Longitude and latitude in the native coordinate system of the projection [deg]. These may refer to the same storage as <i>Ing</i> and <i>lat</i> respectively.	

Returns

Status return value:

• 0: Success.

sphdpa()

Compute angular distance and position angle.

sphdpa() computes the angular distance and generalized position angle (see notes) from a "reference" point to a number of "field" points on the sphere. The points must be specified consistently in any spherical coordinate system.

sphdpa() is complementary to sphpad().

Parameters

i	.n	nfield	The number of field points.	
i	.n	Ing0,lat0	Spherical coordinates of the reference point [deg].	
i	n	Ing,lat	Spherical coordinates of the field points [deg] _{enerated on Tue} May 14 2024 02:34:19 for WCSLIB by Doxygen	
0	ut	dist,pa	Angular distances and position angles [deg]. These may refer to the same storage as Ing and lat respectively.	

Returns

Status return value:

· 0: Success.

Notes:

1. **sphdpa**() uses sphs2x() to rotate coordinates so that the reference point is at the north pole of the new system with the north pole of the old system at zero longitude in the new. The Euler angles required by sphs2x() for this rotation are

```
eul[0] = lng0;
eul[1] = 90.0 - lat0;
eul[2] = 0.0;
```

The angular distance and generalized position angle are readily obtained from the longitude and latitude of the field point in the new system. This applies even if the reference point is at one of the poles, in which case the "position angle" returned is as would be computed for a reference point at $(\alpha_0, +90^\circ - \epsilon)$ or $(\alpha_0, -90^\circ + \epsilon)$, in the limit as ϵ goes to zero.

It is evident that the coordinate system in which the two points are expressed is irrelevant to the determination of the angular separation between the points. However, this is not true of the generalized position angle.

The generalized position angle is here defined as the angle of intersection of the great circle containing the reference and field points with that containing the reference point and the pole. It has its normal meaning when the the reference and field points are specified in equatorial coordinates (right ascension and declination).

Interchanging the reference and field points changes the position angle in a non-intuitive way (because the sum of the angles of a spherical triangle normally exceeds 180°).

The position angle is undefined if the reference and field points are coincident or antipodal. This may be detected by checking for a distance of 0° or 180° (within rounding tolerance). **sphdpa**() will return an arbitrary position angle in such circumstances.

sphpad()

Compute field points offset from a given point.

sphpad() computes the coordinates of a set of points that are offset by the specified angular distances and position angles from a given "reference" point on the sky. The distances and position angles must be specified consistently in any spherical coordinate system.

sphpad() is complementary to sphdpa().

Parameters

in	nfield	The number of field points.	
in	Ing0,lat0	Spherical coordinates of the reference point [deg].	
in	dist,pa	Angular distances and position angles [deg].	
out	Ing,lat	Spherical coordinates of the field points [deg]. These may refer to the same storage as dist	
		and pa respectively.	

Generated on Tue May 14 2024 02:34:19 for WCSLIB by Doxygen

Returns

Status return value:

· 0: Success.

Notes:

1. **sphpad**() is implemented analogously to sphdpa() although using sphx2s() for the inverse transformation. In particular, when the reference point is at one of the poles, "position angle" is interpreted as though the reference point was at $(\alpha_0, +90^{\circ} - \epsilon)$ or $(\alpha_0, -90^{\circ} + \epsilon)$, in the limit as ϵ goes to zero.

Applying **sphpad**() with the distances and position angles computed by **sphdpa**() should return the original field points.

00095 *
                                                                                               native colatitude of the celestial pole [deg].
00096 *
                                                                                       2: Native longitude of the celestial pole [deg].
00097 *
                                                                                       3: cos(eul[1])
00098 *
                                                                                      4: sin(eul[11)
00099 *
00100 *
                         nlng, nlat int
                                                                               Vector lengths.
00101 *
00102 *
                          sll,spt int
                                                                                Vector strides.
00103 *
                          lng,lat const double[]
00104 *
00105 *
                                                                               Celestial longitude and latitude [deg].
00106 *
00107 * Returned:
00108 *
                         phi,theta double[] Longitude and latitude in the native coordinate system
00109 *
                                                                                of the projection [deg]. These may refer to the same % \left( 1\right) =\left( 1\right) \left( 1\right) 
00110 *
                                                                                 storage as lng and lat respectively.
00111 *
00112 * Function return value:
00113 *
                                                                     Status return value:
00114 *
                                                                                      0: Success.
00115 *
00116 *
00117 \star sphdpa() - Compute angular distance and position angle
00118 *
00119 \star sphdpa() computes the angular distance and generalized position angle (see
00120 \star notes) from a "reference" point to a number of "field" points on the sphere.
00121 \star The points must be specified consistently in any spherical coordinate
00122 * system.
00123 *
00124 * sphdpa() is complementary to sphpad().
00125 *
00126 * Given:
                         nfield
00127 *
                                                 int
                                                                               The number of field points.
00128 *
00129 *
                         lng0,lat0 double
                                                                                Spherical coordinates of the reference point [deg].
00130 *
00131 *
                         lng,lat const double[]
00132 *
                                                                                Spherical coordinates of the field points [deg].
00133 *
00134 * Returned:
                                                    double[] Angular distances and position angles [deg]. These
00135 *
                         dist,pa
00136 *
                                                                               may refer to the same storage as lng and lat
00137 *
                                                                                respectively.
00138 *
00139 * Function return value:
00140 *
                                                    int
                                                                                Status return value:
00141 *
                                                                                      0: Success.
00142 *
```

```
00143 * Notes:
00144 \star 1. sphdpa() uses sphs2x() to rotate coordinates so that the reference
00145 *
                             point is at the north pole of the new system with the north pole of the
00146 *
                              old system at zero longitude in the new. The Euler angles required by
00147 *
                             sphs2x() for this rotation are
00148 *
                                  eul[0] = lng0;
00150 =
                                  eul[1] = 90.0 - lat0;
00151 =
                                  eu1[2] = 0.0;
00152 *
00153 *
                             The angular distance and generalized position angle are readily
00154 *
                             obtained from the longitude and latitude of the field point in the new
00155 *
                                                 This applies even if the reference point is at one of the
00156 *
                              poles, in which case the "position angle" returned is as would be
00157 *
                              computed for a reference point at (lng0,+90-epsilon) or
00158 *
                              (lng0, -90 + epsilon), in the limit as epsilon goes to zero.
00159 *
00160 *
                              It is evident that the coordinate system in which the two points are
                              expressed is irrelevant to the determination of the angular separation
00161 *
00162 *
                              between the points. However, this is not true of the generalized
00163 *
                             position angle.
00164 *
00165 *
                              The generalized position angle is here defined as the angle of
00166 *
                              intersection of the great circle containing the reference and field
00167 *
                              points with that containing the reference point and the pole. It has
                              its normal meaning when the the reference and field points are
00168 *
00169 *
                              specified in equatorial coordinates (right ascension and declination).
00170 *
00171 *
                              Interchanging the reference and field points changes the position \mbox{angle}
00172 *
                              in a non-intuitive way (because the sum of the angles of a spherical % \left( 1\right) =\left( 1\right) \left( 1\right) +\left( 1\right) \left( 1\right) \left( 1\right) +\left( 1\right) \left( 
00173 *
                              triangle normally exceeds 180 degrees).
00174 *
00175 *
                              The position angle is undefined if the reference and field points are
00176 *
                              coincident or antipodal. This may be detected by checking for a
00177 *
                              distance of 0 or 180 degrees (within rounding tolerance). sphdpa()
00178 *
                             will return an arbitrary position angle in such circumstances.
00179 *
00180 *
00181 * sphpad() - Compute field points offset from a given point
00182 *
00183 \star sphpad() computes the coordinates of a set of points that are offset by the
00184 \star specified angular distances and position angles from a given "reference"
00185 \star point on the sky. The distances and position angles must be specified
00186 * consistently in any spherical coordinate system.
00187 *
00188 * sphpad() is complementary to sphdpa().
00189 *
00190 * Given:
00191 *
                     nfield
                                                                   The number of field points.
                                          int
00192 *
00193 *
                     lng0,lat0 double
                                                                    Spherical coordinates of the reference point [deg].
00194 *
00195 * dist,pa const double[]
00196 *
                                                                   Angular distances and position angles [deg].
00197 *
00198 * Returned:
00199 * lng,lat
                                          double[] Spherical coordinates of the field points [deg].
00200 *
                                                                    These may refer to the same storage as dist and pa
00201 *
                                                                    respectively.
00202 *
00203 * Function return value:
00204 *
                                                                 Status return value:
                                            int
00205 *
                                                                        0: Success.
00206 *
00207 * Notes:
00208 \star 1: sphpad() is implemented analogously to sphdpa() although using sphx2s()
                             for the inverse transformation. In particular, when the reference point is at one of the poles, "position angle" is interpreted as though
00209 *
00210 *
00211 *
                             the reference point was at (lng0,+90-epsilon) or (lng0,-90+epsilon), in
00212 *
                             the limit as epsilon goes to zero.
00213 *
00214 *
                     Applying sphpad() with the distances and position angles computed by
00215 *
                     sphdpa() should return the original field points.
00216 *

Data Structures

struct spxprm

Spectral variables and their derivatives.

Macros

• #define SPXLEN (sizeof(struct spxprm)/sizeof(int))

Size of the spxprm struct in int units.

• #define SPX_ARGS

For use in declaring spectral conversion function prototypes.

Enumerations

```
    enum spx_errmsg {
        SPXERR_SUCCESS = 0 , SPXERR_NULL_POINTER = 1 , SPXERR_BAD_SPEC_PARAMS = 2 ,
        SPXERR_BAD_SPEC_VAR = 3 ,
        SPXERR_BAD_INSPEC_COORD = 4 }
```

Functions

int specx (const char *type, double spec, double restfrq, double restwav, struct spxprm *specs)

Spectral cross conversions (scalar).

• int spxperr (const struct spxprm *spx, const char *prefix)

Print error messages from a spxprm struct.

int freqafrq (SPX_ARGS)

Status return messages.

Convert frequency to angular frequency (vector).

int afrqfreq (SPX_ARGS)

Convert angular frequency to frequency (vector).

int freqener (SPX_ARGS)

Convert frequency to photon energy (vector).

int enerfreq (SPX_ARGS)

Convert photon energy to frequency (vector).

int freqwavn (SPX_ARGS)

Convert frequency to wave number (vector).

int wavnfreq (SPX_ARGS)

Convert wave number to frequency (vector).

int freqwave (SPX_ARGS)

Convert frequency to vacuum wavelength (vector).

· int wavefreq (SPX_ARGS)

Convert vacuum wavelength to frequency (vector).

int freqawav (SPX_ARGS)

Convert frequency to air wavelength (vector).

• int awayfreq (SPX_ARGS)

Convert air wavelength to frequency (vector).

• int waveawav (SPX_ARGS)

Convert vacuum wavelength to air wavelength (vector).

• int awavwave (SPX_ARGS)

Convert air wavelength to vacuum wavelength (vector).

• int velobeta (SPX_ARGS)

Convert relativistic velocity to relativistic beta (vector).

int betavelo (SPX ARGS)

Convert relativistic beta to relativistic velocity (vector).

int frequelo (SPX ARGS)

Convert frequency to relativistic velocity (vector).

• int velofreq (SPX_ARGS)

Convert relativistic velocity to frequency (vector).

int freqvrad (SPX_ARGS)

Convert frequency to radio velocity (vector).

int vradfreq (SPX_ARGS)

Convert radio velocity to frequency (vector).

• int wavevelo (SPX ARGS)

Conversions between wavelength and velocity types (vector).

int velowave (SPX_ARGS)

Convert relativistic velocity to vacuum wavelength (vector).

int awavvelo (SPX_ARGS)

Convert air wavelength to relativistic velocity (vector).

int veloawav (SPX_ARGS)

Convert relativistic velocity to air wavelength (vector).

int wavevopt (SPX_ARGS)

Convert vacuum wavelength to optical velocity (vector).

int voptwave (SPX_ARGS)

Convert optical velocity to vacuum wavelength (vector).

int wavezopt (SPX_ARGS)

Convert vacuum wavelength to redshift (vector).

int zoptwave (SPX_ARGS)

Convert redshift to vacuum wavelength (vector).

6.19.1 Detailed Description

Routines in this suite implement the spectral coordinate systems recognized by the FITS World Coordinate System (WCS) standard, as described in

```
"Representations of world coordinates in FITS",
Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061 (WCS Paper I)
"Representations of spectral coordinates in FITS",
Greisen, E.W., Calabretta, M.R., Valdes, F.G., & Allen, S.L.
2006, A&A, 446, 747 (WCS Paper III)
```

specx() is a scalar routine that, given one spectral variable (e.g. frequency), computes all the others (e.g. wavelength, velocity, etc.) plus the required derivatives of each with respect to the others. The results are returned in the spxprm struct.

spxperr() prints the error message(s) (if any) stored in a spxprm struct.

The remaining routines are all vector conversions from one spectral variable to another. The API of these functions only differ in whether the rest frequency or wavelength need be supplied.

Non-linear:

- freqwave() frequency -> vacuum wavelength
- wavefreq() vacuum wavelength -> frequency
- freqawav() frequency -> air wavelength
- awavfreq() air wavelength -> frequency
- frequelo() frequency -> relativistic velocity
- velofreq() relativistic velocity -> frequency
- waveawav() vacuum wavelength -> air wavelength
- awavwave() air wavelength -> vacuum wavelength
- wavevelo() vacuum wavelength -> relativistic velocity
- velowave() relativistic velocity -> vacuum wavelength
- awavvelo() air wavelength -> relativistic velocity
- veloawav() relativistic velocity -> air wavelength

Linear:

- freqafrq() frequency -> angular frequency
- afrqfreq() angular frequency -> frequency
- frequency -> energy
- enerfreq() energy -> frequency
- freqwavn() frequency -> wave number
- wavnfreq() wave number -> frequency
- freqvrad() frequency -> radio velocity

- vradfreq() radio velocity -> frequency
- wavevopt() vacuum wavelength -> optical velocity
- voptwave() optical velocity -> vacuum wavelength
- wavezopt() vacuum wavelength -> redshift
- zoptwave() redshift -> vacuum wavelength
- velobeta() relativistic velocity -> beta ($\beta = v/c$)
- betavelo() beta ($\beta = v/c$) -> relativistic velocity

These are the workhorse routines, to be used for fast transformations. Conversions may be done "in place" by calling the routine with the output vector set to the input.

Air-to-vacuum wavelength conversion:

The air-to-vacuum wavelength conversion in early drafts of WCS Paper III cites Cox (ed., 2000, Allen's Astrophysical Quantities, AIP Press, Springer-Verlag, New York), which itself derives from Edlén (1953, Journal of the Optical Society of America, 43, 339). This is the IAU standard, adopted in 1957 and again in 1991. No more recent IAU resolution replaces this relation, and it is the one used by WCSLIB.

However, the Cox relation was replaced in later drafts of Paper III, and as eventually published, by the IUGG relation (1999, International Union of Geodesy and Geophysics, comptes rendus of the 22nd General Assembly, Birmingham UK, p111). There is a nearly constant ratio between the two, with IUGG/Cox = 1.000015 over most of the range between 200nm and 10,000nm.

The IUGG relation itself is derived from the work of Ciddor (1996, Applied Optics, 35, 1566), which is used directly by the Sloan Digital Sky Survey. It agrees closely with Cox; longwards of 2500nm, the ratio Ciddor/Cox is fixed at 1.000000021, decreasing only slightly, to 1.000000018, at 1000nm.

The Cox, IUGG, and Ciddor relations all accurately provide the wavelength dependence of the air-to-vacuum wavelength conversion. However, for full accuracy, the atmospheric temperature, pressure, and partial pressure of water vapour must be taken into account. These will determine a small, wavelength-independent scale factor and offset, which is not considered by WCS Paper III.

WCS Paper III is also silent on the question of the range of validity of the air-to-vacuum wavelength conversion. Cox's relation would appear to be valid in the range 200nm to 10,000nm. Both the Cox and the Ciddor relations have singularities below 200nm, with Cox's at 156nm and 83nm. WCSLIB checks neither the range of validity, nor for these singularities.

Argument checking:

The input spectral values are only checked for values that would result in floating point exceptions. In particular, negative frequencies and wavelengths are allowed, as are velocities greater than the speed of light. The same is true for the spectral parameters - rest frequency and wavelength.

Accuracy:

No warranty is given for the accuracy of these routines (refer to the copyright notice); intending users must satisfy for themselves their adequacy for the intended purpose. However, closure effectively to within double precision rounding error was demonstrated by test routine tspec.c which accompanies this software.

6.19.2 Macro Definition Documentation

SPXLEN

```
#define SPXLEN (sizeof(struct spxprm)/sizeof(int))
```

Size of the spxprm struct in int units.

Size of the spxprm struct in int units, used by the Fortran wrappers.

SPX_ARGS

```
#define SPX_ARGS
```

Value:

```
double param, int nspec, int instep, int outstep, \
const double inspec[], double outspec[], int stat[]
```

For use in declaring spectral conversion function prototypes.

Preprocessor macro used for declaring spectral conversion function prototypes.

6.19.3 Enumeration Type Documentation

spx_errmsg

```
enum const char * spx_errmsg[]
```

Status return messages.

Error messages to match the status value returned from each function.

Enumerator

SPXERR_SUCCESS	
SPXERR_NULL_POINTER	
SPXERR_BAD_SPEC_PARAMS	
SPXERR_BAD_SPEC_VAR	
SPXERR_BAD_INSPEC_COORD	

6.19.4 Function Documentation

specx()

Spectral cross conversions (scalar).

Given one spectral variable **specx**() computes all the others, plus the required derivatives of each with respect to the others.

Parameters

in	type	The type of spectral variable given by spec, FREQ, AFRQ, ENER, WAVN, VRAD, WAVE, VOPT, ZOPT, AWAV, VELO, or BETA (case sensitive).	
in	spec	The spectral variable given, in SI units.	

Parameters

in	restfrq,restwav	Rest frequency [Hz] or rest wavelength in vacuo [m], only one of which need be given. The other should be set to zero. If both are zero, only a subset of the spectral variables can be computed, the remainder are set to zero. Specifically, given one of FREQ, AFRQ, ENER, WAVN, WAVE, or AWAV the others can be computed without knowledge of the rest frequency. Likewise, VRAD, VOPT, ZOPT, VELO, and BETA.
in,out	specs	Data structure containing all spectral variables and their derivatives, in SI units.

Returns

Status return value:

- 0: Success.
- 1: Null spxprm pointer passed.
- 2: Invalid spectral parameters.
- 3: Invalid spectral variable.

For returns > 1, a detailed error message is set in spxprm::err if enabled, see wcserr_enable().

freqafrq(), afrqfreq(), freqener(), enerfreq(), freqwavn(), wavnfreq(), freqwave(), wavefreq(), freqawav(), awavfreq(), waveawav(), awavwave(), velobeta(), and betavelo() implement vector conversions between wave-like or velocity-like spectral types (i.e. conversions that do not need the rest frequency or wavelength). They all have the same API.

spxperr()

Print error messages from a spxprm struct.

spxperr() prints the error message(s) (if any) stored in a spxprm struct. If there are no errors then nothing is printed. It uses wcserr_prt(), q.v.

Parameters

in	spx	Spectral variables and their derivatives.	
in	prefix	If non-NULL, each output line will be prefixed with this string.	

Returns

Status return value:

- 0: Success.
- 1: Null spxprm pointer passed.

freqafrq()

```
int freqafrq (
          SPX_ARGS )
```

Convert frequency to angular frequency (vector).

freqafrq() converts frequency to angular frequency.

Parameters

in	param	Ignored.
in	nspec	Vector length.
in	instep,outstep	Vector strides.
in	inspec	Input spectral variables, in SI units.
out	outspec	Output spectral variables, in SI units.
out	stat	Status return value for each vector element: • 0: Success. • 1: Invalid value of inspec.

Returns

Status return value:

- 0: Success.
- 2: Invalid spectral parameters.
- 4: One or more of the inspec coordinates were invalid, as indicated by the stat vector.

afrqfreq()

Convert angular frequency to frequency (vector).

afrqfreq() converts angular frequency to frequency.

See freqafrq() for a description of the API.

freqener()

```
int freqener (

SPX_ARGS )
```

Convert frequency to photon energy (vector).

frequency to photon energy.

See freqafrq() for a description of the API.

enerfreq()

Convert photon energy to frequency (vector).

enerfreq() converts photon energy to frequency.

See freqafrq() for a description of the API.

freqwavn()

Convert frequency to wave number (vector).

freqwavn() converts frequency to wave number.

See freqafrq() for a description of the API.

wavnfreq()

Convert wave number to frequency (vector).

wavnfreq() converts wave number to frequency.

See freqafrq() for a description of the API.

freqwave()

```
int freqwave (
          SPX_ARGS )
```

Convert frequency to vacuum wavelength (vector).

freqwave() converts frequency to vacuum wavelength.

See freqafrq() for a description of the API.

wavefreq()

```
int wavefreq (
SPX_ARGS )
```

Convert vacuum wavelength to frequency (vector).

wavefreq() converts vacuum wavelength to frequency.

See freqafrq() for a description of the API.

freqawav()

Convert frequency to air wavelength (vector).

freqawav() converts frequency to air wavelength.

See freqafrq() for a description of the API.

awavfreq()

Convert air wavelength to frequency (vector).

awavfreq() converts air wavelength to frequency.

See freqafrq() for a description of the API.

waveawav()

```
int waveawav (
SPX_ARGS )
```

Convert vacuum wavelength to air wavelength (vector).

waveawav() converts vacuum wavelength to air wavelength.

See freqafrq() for a description of the API.

awavwave()

Convert air wavelength to vacuum wavelength (vector).

awavwave() converts air wavelength to vacuum wavelength.

See freqafrq() for a description of the API.

velobeta()

```
int velobeta (

SPX_ARGS )
```

Convert relativistic velocity to relativistic beta (vector).

velobeta() converts relativistic velocity to relativistic beta.

See freqafrq() for a description of the API.

betavelo()

```
int betavelo (
          SPX_ARGS )
```

Convert relativistic beta to relativistic velocity (vector).

betavelo() converts relativistic beta to relativistic velocity.

See freqafrq() for a description of the API.

freqvelo()

Convert frequency to relativistic velocity (vector).

freqvelo() converts frequency to relativistic velocity.

Parameters

in	param	Rest frequency [Hz].
in	nspec	Vector length.
in	instep,outstep	Vector strides.
in	inspec	Input spectral variables, in SI units.
out	outspec	Output spectral variables, in SI units.
out	stat	Status return value for each vector element: • 0: Success. • 1: Invalid value of inspec.

Returns

Status return value:

- 0: Success.
- 2: Invalid spectral parameters.
- 4: One or more of the inspec coordinates were invalid, as indicated by the stat vector.

velofreq()

Convert relativistic velocity to frequency (vector).

velofreq() converts relativistic velocity to frequency.

See freqvelo() for a description of the API.

freqvrad()

```
int freqvrad (
          SPX_ARGS )
```

Convert frequency to radio velocity (vector).

freqvrad() converts frequency to radio velocity.

See freqvelo() for a description of the API.

vradfreq()

Convert radio velocity to frequency (vector).

vradfreq() converts radio velocity to frequency.

See freqvelo() for a description of the API.

wavevelo()

```
int wavevelo (
SPX_ARGS )
```

Conversions between wavelength and velocity types (vector).

 $\textbf{wavevelo}() \ \text{converts vacuum wavelength to relativistic velocity}.$

Parameters

in	param	Rest wavelength in vacuo [m].
in	nspec	Vector length.
in	instep,outstep	Vector strides.
in	inspec	Input spectral variables, in SI units.
out	outspec	Output spectral variables, in SI units.
out	stat	Status return value for each vector element: • 0: Success.
		1: Invalid value of inspec.

Returns

Status return value:

- 0: Success.
- 2: Invalid spectral parameters.
- 4: One or more of the inspec coordinates were invalid, as indicated by the stat vector.

velowave()

Convert relativistic velocity to vacuum wavelength (vector).

velowave() converts relativistic velocity to vacuum wavelength.

See freqvelo() for a description of the API.

awavvelo()

```
int awavvelo (
          SPX_ARGS )
```

Convert air wavelength to relativistic velocity (vector).

awavvelo() converts air wavelength to relativistic velocity.

See freqvelo() for a description of the API.

veloawav()

```
int veloawav (
SPX_ARGS )
```

Convert relativistic velocity to air wavelength (vector).

veloawav() converts relativistic velocity to air wavelength.

See freqvelo() for a description of the API.

wavevopt()

Convert vacuum wavelength to optical velocity (vector).

wavevopt() converts vacuum wavelength to optical velocity.

See freqvelo() for a description of the API.

voptwave()

```
int voptwave (
SPX_ARGS )
```

Convert optical velocity to vacuum wavelength (vector).

voptwave() converts optical velocity to vacuum wavelength.

See freqvelo() for a description of the API.

wavezopt()

Convert vacuum wavelength to redshift (vector).

wavevopt() converts vacuum wavelength to redshift.

See freqvelo() for a description of the API.

zoptwave()

```
int zoptwave (
SPX_ARGS )
```

Convert redshift to vacuum wavelength (vector).

zoptwave() converts redshift to vacuum wavelength.

See frequelo() for a description of the API.

00038 =
           "Representations of spectral coordinates in FITS",
           Greisen, E.W., Calabretta, M.R., Valdes, F.G., & Allen, S.L.
00040 =
           2006, A&A, 446, 747 (WCS Paper III)
00041 *
00042 \star specx() is a scalar routine that, given one spectral variable (e.g.
00043 \star \text{frequency}), computes all the others (e.g. wavelength, velocity, etc.) plus 00044 \star \text{the required derivatives of each with respect to the others. The results}
00045 * are returned in the spxprm struct.
00046 *
00047 \star spxperr() prints the error message(s) (if any) stored in a spxprm struct.
00048 *
00049 * The remaining routines are all vector conversions from one spectral 00050 * variable to another. The API of these functions only differ in whether the
00051 * rest frequency or wavelength need be supplied.
00052
00053 * Non-linear:
00054 * - freqwave()
                              frequency
                                                         -> vacuum wavelength
00055 *
           - wavefreq()
                             vacuum wavelength
                                                        -> frequency
00056 *
00057 *
           - freqawav()
                                                         -> air wavelength
                              frequency
00058 *
           - awavfreq()
                              air wavelength
                                                         -> frequency
00059 *
00060 *
           - frequelo()
                                                         -> relativistic velocity
                              frequency
                              relativistic velocity -> frequency
           - velofreq()
00061 *
00062 *
00063 *
                              vacuum wavelength
           - waveawav()
                                                        -> air wavelength
00064 *

00092 *
           - betavelo()
                              beta (= v/c)
                                                         -> relativistic velocity
00093 *
00094 \star These are the workhorse routines, to be used for fast transformations. 00095 \star Conversions may be done "in place" by calling the routine with the output
00096 * vector set to the input.
00097 *
00098 \star Air-to-vacuum wavelength conversion:
00099 * --
00100 * The air-to-vacuum wavelength conversion in early drafts of WCS Paper III
00101 * cites Cox (ed., 2000, Allen's Astrophysical Quantities, AIP Press,
00102 * Springer-Verlag, New York), which itself derives from Edlén (1953, Journal
00103 \star of the Optical Society of America, 43, 339). This is the IAU standard, 00104 \star adopted in 1957 and again in 1991. No more recent IAU resolution replaces
00105 \star this relation, and it is the one used by WCSLIB.
00106 *
00107 \star However, the Cox relation was replaced in later drafts of Paper III, and as
00108 \star eventually published, by the IUGG relation (1999, International Union of
00109 * Geodesy and Geophysics, comptes rendus of the 22nd General Assembly,
00110 * Birmingham UK, pll1). There is a nearly constant ratio between the two
00111 * with \overline{IUGG/Cox} = 1.000015 over most of the range between 200nm and 10,000nm.
00112 *
00113 * The IUGG relation itself is derived from the work of Ciddor (1996, Applied
00114 * Optics, 35, 1566), which is used directly by the Sloan Digital Sky Survey.
00115 * It agrees closely with Cox; longwards of 2500nm, the ratio Ciddor/Cox is
00116 \star fixed at 1.000000021, decreasing only slightly, to 1.000000018, at 1000nm.
00117
00118 \star The Cox, IUGG, and Ciddor relations all accurately provide the wavelength 00119 \star dependence of the air-to-vacuum wavelength conversion. However, for full
```

```
00120 \star accuracy, the atmospheric temperature, pressure, and partial pressure of
00121 * water vapour must be taken into account. These will determine a small,
00122 \star wavelength-independent scale factor and offset, which is not considered by
00123 * WCS Paper III.
00124 *
00125 \star WCS Paper III is also silent on the question of the range of validity of the
00126 * air-to-vacuum wavelength conversion. Cox's relation would appear to be 00127 * valid in the range 200nm to 10,000nm. Both the Cox and the Ciddor relations
00128 \star have singularities below 200nm, with Cox's at 156nm and 83nm. WCSLIB checks
00129 \star neither the range of validity, nor for these singularities.
00130 *
00131 * Argument checking:
00132 *
00133 \star The input spectral values are only checked for values that would result
00134 \star in floating point exceptions. In particular, negative frequencies and
00135 \star wavelengths are allowed, as are velocities greater than the speed of
00136 \star light. The same is true for the spectral parameters - rest frequency and
00137 * wavelength.
00139 * Accuracy:
00140 *
00141 \star No warranty is given for the accuracy of these routines (refer to the
00142 \star copyright notice); intending users must satisfy for themselves their
00143 \star adequacy for the intended purpose. However, closure effectively to within
00144 * double precision rounding error was demonstrated by test routine tspec.c
00145 * which accompanies this software.
00146 *
00147 *
00148 * specx() - Spectral cross conversions (scalar)
00149 *
00150 * Given one spectral variable specx() computes all the others, plus the
00151 * required derivatives of each with respect to the others.
00152 *
00153 * Given:
00154 *
                    const char*
                               The type of spectral variable given by spec, FREQ,
00155 *
                               AFRQ, ENER, WAVN, VRAD, WAVE, VOPT, ZOPT, AWAV, VELO,
00156 *
00157 *
                               or BETA (case sensitive).
00158 *
00159 *
                    double
                               The spectral variable given, in SI units.
00160 *
          restfrq,
00161 *
00162 *
                               Rest frequency [Hz] or rest wavelength in vacuo [m],
          restway
                    double
00163 *
                               only one of which need be given. The other should be
                                set to zero. If both are zero, only a subset of the
00164 *
00165 *
                                spectral variables can be computed, the remainder are
00166 *
                                set to zero. Specifically, given one of FREQ, AFRQ,
                               ENER, WAVN, WAVE, or AWAV the others can be computed without knowledge of the rest frequency. Likewise,
00167 *
00168 *
                               VRAD, VOPT, ZOPT, VELO, and BETA.
00169 *
00171 * Given and returned:
         specs struct spxprm*
00172 *
00173 *
                               Data structure containing all spectral variables and
00174 *
                               their derivatives, in SI units.
00175 *
00176 * Function return value:
00177 *
                               Status return value:
00178 *
                                 0: Success.
00179 *
                                 1: Null spxprm pointer passed.
00180 *
                                 2: Invalid spectral parameters.
00181 *
                                 3: Invalid spectral variable.
00182 *
00183 *
                               For returns > 1, a detailed error message is set in
00184 *
                               spxprm::err if enabled, see wcserr_enable().
00185 *
00186 * freqafrq(), afrqfreq(), freqener(), enerfreq(), freqwavn(), wavnfreq(),
00187 * freqwave(), wavefreq(), freqawav(), awavfreq(), waveawav(), awavwave(),
00188 * velobeta(), and betavelo() implement vector conversions between wave-like
00189 \star or velocity-like spectral types (i.e. conversions that do not need the rest
00190 \star frequency or wavelength). They all have the same API.
00191 *
00192 *
00193 * spxperr() - Print error messages from a spxprm struct
00194 *
00195 \star spxperr() prints the error message(s) (if any) stored in a spxprm struct.
00196 * If there are no errors then nothing is printed. It uses wcserr_prt(), q.v.
00197 *
00198 * Given:
00199 *
                   const struct spxprm*
         spx
00200 *
                               Spectral variables and their derivatives.
00202 *
                  const char *
                               If non-NULL, each output line will be prefixed with
00203 *
00204 *
                               this string.
00205 *
00206 * Function return value:
```

```
int
                                Status return value:
                                  0: Success.
00208 *
00209 *
                                  1: Null spxprm pointer passed.
00210 *
00211 *
00212 * freqafrq() - Convert frequency to angular frequency (vector)
00214 * freqafrq() converts frequency to angular frequency.
00215 *
00216 * Given:
          param
00217 *
                    double
                               Ignored.
00218 *
00219 *
          nspec
                    int
                                Vector length.

          inspec
00225 *
                                Input spectral variables, in SI units.
00226 *
00227 * Returned:
00228 *
          outspec
                     double[] Output spectral variables, in SI units.
00229 *
                                Status return value for each vector element:
00230 *
          stat
                     int[]
00231 *
                                  0: Success.
00232 *
                                  1: Invalid value of inspec.
00233 *
00234 * Function return value:
00235 *
                     int
                                Status return value:
00236 *
                                  0: Success.
00237 *
                                  2: Invalid spectral parameters.
00238 *
                                  4: One or more of the inspec coordinates were
00239 *
                                     invalid, as indicated by the stat vector.
00240 *
00241
00241 * 00242 * freqvelo(), velofreq(), freqvrad(), and vradfreq() implement vector 00243 * conversions between frequency and velocity spectral types. They all have
00244 \star the same API.
00245 *
00246 *
00247 \star frequelo() - Convert frequency to relativistic velocity (vector)
00248 *
00249 * frequelo() converts frequency to relativistic velocity.
00250 *
00251 * Given:
00252 *
          param
                     double
                               Rest frequency [Hz].
00253 *
                             Vector length.
00254 *
          nspec
                    int.
00255 *
00256 *

00292 *
          outstep
                     int
                                Vector strides.
00293 *
```

```
00294 *
                   const double[]
         inspec
00295 *
                              Input spectral variables, in SI units.
00296 *
00297 * Returned:
00298 *
         outspec
                    double[] Output spectral variables, in SI units.
00299 *
00300 *
         stat
                    int[]
                              Status return value for each vector element:
00301 *
                                 0: Success.
00302 *
                                1: Invalid value of inspec.
00303 *
00304 * Function return value:
00305 *
                   int
                              Status return value:
00306 *
                                0: Success.
00307 *
                                 2: Invalid spectral parameters.
00308 *
                                 4: One or more of the inspec coordinates were
00309 *
                                   invalid, as indicated by the stat vector.
00310 *
00311 *
00312 * spxprm struct - Spectral variables and their derivatives
00313 *
00314 \star The spxprm struct contains the value of all spectral variables and their
00315 * derivatives.
                      It is used solely by specx() which constructs it from
00316 \star information provided via its function arguments.
00317 *
00318 \star This struct should be considered read-only, no members need ever be set nor
00319 \star should ever be modified by the user.
00320 *
00321 *
         double restfrq
00322 *
            (Returned) Rest frequency [Hz].
00323 *
00324 *
         double restway
00325 *
            (Returned) Rest wavelength [m].
00326 *
00327 *
         int wavetype
00328 *
            (Returned) True if wave types have been computed, and ...
00329 *
00330 *
         int velotype
00331 *
            (Returned) ... true if velocity types have been computed; types are
00332 *
           defined below.
00333 *
00334 *
           If one or other of spxprm::restfrq and spxprm::restwav is given
00335 *
            (non-zero) then all spectral variables may be computed. If both are
00336 *
            given, restfrq is used. If restfrq and restwav are both zero, only wave
            characteristic xor velocity type spectral variables may be computed
00337 *
00338 *
                                               These flags indicate what is
            depending on the variable given.
00339 *
            available.
00340 *

Enumerations

```
    enum tabenq_enum { TABENQ_MEM = 1 , TABENQ_SET = 2 , TABENQ_BYP = 4 }
    enum tab_errmsg_enum {
        TABERR_SUCCESS = 0 , TABERR_NULL_POINTER = 1 , TABERR_MEMORY = 2 , TABERR_BAD_PARAMS = 3 ,
        TABERR_BAD_X = 4 , TABERR_BAD_WORLD = 5 }
```

Functions

• int tabini (int alloc, int M, const int K[], struct tabprm *tab)

Default constructor for the tabprm struct.

int tabmem (struct tabprm *tab)

Acquire tabular memory.

• int tabcpy (int alloc, const struct tabprm *tabsrc, struct tabprm *tabdst)

Copy routine for the tabprm struct.

• int tabcmp (int cmp, double tol, const struct tabprm *tab1, const struct tabprm *tab2, int *equal)

Compare two tabprm structs for equality.

int tabfree (struct tabprm *tab)

Destructor for the tabprm struct.

int tabsize (const struct tabprm *tab, int size[2])

Compute the size of a tabprm struct.

int tabenq (const struct tabprm *tab, int enquiry)

enquire about the state of a tabprm struct.

int tabprt (const struct tabprm *tab)

Print routine for the tabprm struct.

int tabperr (const struct tabprm *tab, const char *prefix)

Print error messages from a tabprm struct.

int tabset (struct tabprm *tab)

Setup routine for the tabprm struct.

int tabx2s (struct tabprm *tab, int ncoord, int nelem, const double x[], double world[], int stat[])

Pixel-to-world transformation

int tabs2x (struct tabprm *tab, int ncoord, int nelem, const double world[], double x[], int stat[])

World-to-pixel transformation.

Variables

const char * tab_errmsg []

Status return messages.

6.21.1 Detailed Description

Routines in this suite implement the part of the FITS World Coordinate System (WCS) standard that deals with tabular coordinates, i.e. coordinates that are defined via a lookup table, as described in

```
"Representations of world coordinates in FITS",
Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061 (WCS Paper I)
"Representations of spectral coordinates in FITS",
Greisen, E.W., Calabretta, M.R., Valdes, F.G., & Allen, S.L.
2006, A&A, 446, 747 (WCS Paper III)
```

These routines define methods to be used for computing tabular world coordinates from intermediate world coordinates (a linear transformation of image pixel coordinates), and vice versa. They are based on the tabprm struct which contains all information needed for the computations. The struct contains some members that must be set by the user, and others that are maintained by these routines, somewhat like a C++ class but with no encapsulation.

tabini(), tabmem(), tabcpy(), and tabfree() are provided to manage the tabprm struct, tabsize() computes its total size including allocated memory, tabenq() returns information about the state of the struct, and tabprt() prints its contents.

tabperr() prints the error message(s) (if any) stored in a tabprm struct.

A setup routine, tabset(), computes intermediate values in the tabprm struct from parameters in it that were supplied by the user. The struct always needs to be set up by tabset() but it need not be called explicitly - refer to the explanation of tabprm::flag.

tabx2s() and tabs2x() implement the WCS tabular coordinate transformations.

Accuracy:

No warranty is given for the accuracy of these routines (refer to the copyright notice); intending users must satisfy for themselves their adequacy for the intended purpose. However, closure effectively to within double precision rounding error was demonstrated by test routine ttab.c which accompanies this software.

6.21.2 Macro Definition Documentation

TABLEN

```
#define TABLEN (sizeof(struct tabprm)/sizeof(int))
```

Size of the tabprm struct in int units.

Size of the tabprm struct in int units, used by the Fortran wrappers.

tabini_errmsg

```
#define tabini_errmsg tab_errmsg
```

Deprecated.

Deprecated Added for backwards compatibility, use tab_errmsg directly now instead.

tabcpy errmsg

```
#define tabcpy_errmsg tab_errmsg
```

Deprecated.

Deprecated Added for backwards compatibility, use tab_errmsg directly now instead.

6.21 tab.h File Reference 287

tabfree_errmsg

#define tabfree_errmsg tab_errmsg

Deprecated.

Deprecated Added for backwards compatibility, use tab_errmsg directly now instead.

tabprt_errmsg

#define tabprt_errmsg tab_errmsg

Deprecated.

Deprecated Added for backwards compatibility, use tab_errmsg directly now instead.

tabset_errmsg

#define tabset_errmsg tab_errmsg

Deprecated.

Deprecated Added for backwards compatibility, use tab_errmsg directly now instead.

tabx2s_errmsg

#define tabx2s_errmsg tab_errmsg

Deprecated.

Deprecated Added for backwards compatibility, use tab_errmsg directly now instead.

tabs2x_errmsg

#define tabs2x_errmsg tab_errmsg

Deprecated.

Deprecated Added for backwards compatibility, use tab_errmsg directly now instead.

TABERR_MEMORY	
TABERR_BAD_PARAMS	
TABERR_BAD_X	
TABERR_BAD_WORLD	

6.21.4 Function Documentation

tabini()

```
int tabini (
                int alloc,
                int M,
                const int K[],
                struct tabprm * tab )
```

Default constructor for the tabprm struct.

tabini() allocates memory for arrays in a tabprm struct and sets all members of the struct to default values.

PLEASE NOTE: every tabprm struct should be initialized by **tabini**(), possibly repeatedly. On the first invokation, and only the first invokation, the flag member of the tabprm struct must be set to -1 to initialize memory management, regardless of whether **tabini**() will actually be used to allocate memory.

Parameters

in	alloc	If true, allocate memory unconditionally for arrays in the tabprm struct. If false, it is assumed that pointers to these arrays have been set by the user except if they are null pointers in which case memory will be allocated for them regardless. (In other words, setting alloc true saves having to initalize these pointers to zero.)
in	М	The number of tabular coordinate axes.
in	К	Vector of length M whose elements (K_1,K_2,K_M) record the lengths of the axes of the coordinate array and of each indexing vector. M and K[] are used to determine the length of the various tabprm arrays and therefore the amount of memory to allocate for them. Their values are copied into the tabprm struct. It is permissible to set K (i.e. the address of the array) to zero which has the same effect as setting each element of K[] to zero. In this case no memory will be allocated for the index vectors or coordinate array in the tabprm struct. These together with the K vector must be set separately before calling tabset().

6.21 tab.h File Reference 289

Parameters

in,out	tab	Tabular transformation parameters. Note that, in order to initialize memory management
		tabprm::flag should be set to -1 when tab is initialized for the first time (memory leaks may
		result if it had already been initialized).

Returns

Status return value:

- · 0: Success.
- 1: Null tabprm pointer passed.
- 2: Memory allocation failed.
- · 3: Invalid tabular parameters.

For returns > 1, a detailed error message is set in tabprm::err if enabled, see wcserr_enable().

tabmem()

Acquire tabular memory.

tabmem() takes control of memory allocated by the user for arrays in the tabprm struct.

Parameters

in,out	tab	Tabular transformation parameters.
--------	-----	------------------------------------

Returns

Status return value:

- 0: Success.
- 1: Null tabprm pointer passed.
- 2: Memory allocation failed.

For returns > 1, a detailed error message is set in tabprm::err if enabled, see wcserr_enable().

tabcpy()

Copy routine for the tabprm struct.

tabcpy() does a deep copy of one tabprm struct to another, using tabini() to allocate memory for its arrays if required. Only the "information to be provided" part of the struct is copied; a call to tabset() is required to set up the remainder.

Parameters

in	alloc	If true, allocate memory unconditionally for arrays in the tabprm struct. If false, it is assumed that pointers to these arrays have been set by the user except if they are null pointers in which case memory will be allocated for them regardless. (In other words, setting alloc true saves having to initalize these pointers to zero.)
in	tabsrc	Struct to copy from.
in,out	tabdst	Struct to copy to. tabprm::flag should be set to -1 if tabdst was not previously initialized (memory leaks may result if it was previously initialized).

Returns

Status return value:

- 0: Success.
- 1: Null tabprm pointer passed.
- 2: Memory allocation failed.

For returns > 1, a detailed error message is set in tabprm::err (associated with tabdst) if enabled, see wcserr_enable().

tabcmp()

```
int tabcmp (
        int cmp,
        double tol,
        const struct tabprm * tab1,
        const struct tabprm * tab2,
        int * equal )
```

Compare two tabprm structs for equality.

tabcmp() compares two tabprm structs for equality.

Parameters

in	стр	A bit field controlling the strictness of the comparison. At present, this value must always be 0, indicating a strict comparison. In the future, other options may be added.
in	tol	Tolerance for comparison of floating-point values. For example, for tol == 1e-6, all floating-point values in the structs must be equal to the first 6 decimal places. A value of 0 implies exact equality.
in	tab1	The first tabprm struct to compare.
in	tab2	The second tabprm struct to compare.
out	equal	Non-zero when the given structs are equal.

Returns

Status return value:

- 0: Success.
- 1: Null pointer passed.

6.21 tab.h File Reference 291

tabfree()

```
int tabfree ( {\tt struct\ tabprm\ *\ tab}\ )
```

Destructor for the tabprm struct.

tabfree() frees memory allocated for the tabprm arrays by **tabini(**). **tabini(**) records the memory it allocates and **tabfree**() will only attempt to free this.

PLEASE NOTE: tabfree() must not be invoked on a tabprm struct that was not initialized by tabini().

Parameters

out	tab	Coordinate transformation parameters.
-----	-----	---------------------------------------

Returns

Status return value:

- 0: Success.
- 1: Null tabprm pointer passed.

tabsize()

```
int tabsize ( \label{eq:const_struct_tabprm} \mbox{const struct tabprm} \mbox{ * } tab, \\ \mbox{int } size[2] \mbox{ )}
```

Compute the size of a tabprm struct.

tabsize() computes the full size of a tabprm struct, including allocated memory.

Parameters

in	tab	Tabular transformation parameters.
		If NULL, the base size of the struct and the allocated size are both set to zero.
out	sizes	The first element is the base size of the struct as returned by sizeof(struct tabprm). The
		second element is the total allocated size, in bytes, assuming that the allocation was done by
		tabini(). This figure includes memory allocated for the constituent struct, tabprm::err.
		It is not an error for the struct not to have been set up via tabset(), which normally results in
		additional memory allocation.

Returns

Status return value:

• 0: Success.

tabenq()

```
int tabenq (
```

```
const struct tabprm * tab,
int enquiry )
```

enquire about the state of a tabprm struct.

tabenq() may be used to obtain information about the state of a tabprm struct. The function returns a true/false answer for the enquiry asked.

Parameters

in	tab	Tabular transformation parameters.
in	enquiry	Enquiry according to the following parameters:
		TABENQ_MEM: memory in the struct is being managed by WCSLIB (see tabini()).
		 TABENQ_SET: the struct has been set up by tabset().
		 TABENQ_BYP: the struct is in bypass mode (see tabset()).
		These may be combined by logical OR, e.g. TABENQ_MEM TABENQ_SET. The enquiry result will be the logical AND of the individual results.

Returns

Enquiry result:

- 0: No.
- 1: Yes.

tabprt()

```
int tabprt ( {\tt const\ struct\ tabprm\ *\ tab}\ )
```

Print routine for the tabprm struct.

tabprt() prints the contents of a tabprm struct using wcsprintf(). Mainly intended for diagnostic purposes.

Parameters

in	tab	Tabular transformation parameters.

Returns

Status return value:

- 0: Success.
- 1: Null tabprm pointer passed.

tabperr()

6.21 tab.h File Reference 293

Print error messages from a tabprm struct.

tabperr() prints the error message(s) (if any) stored in a tabprm struct. If there are no errors then nothing is printed. It uses wcserr_prt(), q.v.

Parameters

in	tab	Tabular transformation parameters.
in	prefix	If non-NULL, each output line will be prefixed with this string.

Returns

Status return value:

- 0: Success.
- · 1: Null tabprm pointer passed.

tabset()

Setup routine for the tabprm struct.

tabset() allocates memory for work arrays in the tabprm struct and sets up the struct according to information supplied within it.

Note that this routine need not be called directly; it will be invoked by tabx2s() and tabs2x() if tabprm::flag is anything other than a predefined magic value.

tabset() normally operates regardless of the value of tabprm::flag; i.e. even if a struct was previously set up it will be reset unconditionally. However, a tabprm struct may be put into "bypass" mode by invoking **tabset**() initially with tabprm::flag == 1 (rather than 0). **tabset**() will return immediately if invoked on a struct in that state. To take a struct out of bypass mode, simply reset tabprm::flag to zero. See also tabenq().

Parameters

_			
	in,out	tab	Tabular transformation parameters.

Returns

Status return value:

- 0: Success.
- 1: Null tabprm pointer passed.
- · 3: Invalid tabular parameters.

For returns > 1, a detailed error message is set in tabprm::err if enabled, see wcserr_enable().

tabx2s()

Pixel-to-world transformation.

tabx2s() transforms intermediate world coordinates to world coordinates using coordinate lookup.

Parameters

in,out	tab	Tabular transformation parameters.
in	ncoord,nelem	The number of coordinates, each of vector length nelem.
in	Х	Array of intermediate world coordinates, SI units.
out	world	Array of world coordinates, in SI units.
out	stat	Status return value status for each coordinate:
		0: Success.1: Invalid intermediate world coordinate.

Returns

Status return value:

- 0: Success.
- 1: Null tabprm pointer passed.
- 3: Invalid tabular parameters.
- 4: One or more of the x coordinates were invalid, as indicated by the stat vector.

For returns > 1, a detailed error message is set in tabprm::err if enabled, see wcserr_enable().

tabs2x()

World-to-pixel transformation.

tabs2x() transforms world coordinates to intermediate world coordinates.

Parameters

in,out	tab Tabular transformation parameters.	
in	ncoord,nelem	The number of coordinates, each of vector length nelem.
in	world	Array of world coordinates, in SI units.
out	X	Array of intermediate world coordinates, SI units.
out	stat	Status return value status for each vector element:
		0: Success.1: Invalid world coordinate.

Returns

Status return value:

- 0: Success.
- 1: Null tabprm pointer passed.
- · 3: Invalid tabular parameters.
- 5: One or more of the world coordinates were invalid, as indicated by the stat vector.

For returns > 1, a detailed error message is set in tabprm::err if enabled, see wcserr enable().

6.21.5 Variable Documentation

tab errmsg

```
const char * tab_errmsg[] [extern]
```

Status return messages.

Error messages to match the status value returned from each function.

6.22 tab.h

00023 *======
00024 *
```

```
00025 \star WCSLIB 8.3 - C routines that implement the FITS World Coordinate System
00026 \star (WCS) standard. Refer to the README file provided with WCSLIB for an 00027 \star overview of the library.
00028 *
00029 *
00030 * Summary of the tab routines
00032 \star Routines in this suite implement the part of the FITS World Coordinate
00033 \star System (WCS) standard that deals with tabular coordinates, i.e. coordinates
00034 \star that are defined via a lookup table, as described in
00035 *
00036 =
           Representations of world coordinates in FITS"
00037 =
          Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061 (WCS Paper I)
00038 =
00039 =
          "Representations of spectral coordinates in FITS",
          Greisen, E.W., Calabretta, M.R., Valdes, F.G., & Allen, S.L. 2006, A&A, 446, 747 (WCS Paper III)
00040 =
00041 =
00042 *
00043 \star These routines define methods to be used for computing tabular world
00044 \star coordinates from intermediate world coordinates (a linear transformation
00045 \, \star \, \text{of image pixel coordinates}), and vice versa. They are based on the tabprm
00046 \star struct which contains all information needed for the computations. The
00047 \star struct contains some members that must be set by the user, and others that
00048 \star are maintained by these routines, somewhat like a C++ class but with no
00049 * encapsulation.
00050 *
00051 \star tabini(), tabmem(), tabcpy(), and tabfree() are provided to manage the
00052 \star tabprm struct, tabsize() computes its total size including allocated memory,
00053 \star tabenq() returns information about the state of the struct, and tabprt()
00054 * prints its contents.
00055 *
00056 \star tabperr() prints the error message(s) (if any) stored in a tabprm struct.
00057 *
00058 \star A setup routine, tabset(), computes intermediate values in the tabprm struct
00059 \star from parameters in it that were supplied by the user. The struct always
00060 \star needs to be set up by tabset() but it need not be called explicitly - refer 00061 \star to the explanation of tabprm::flag.
00063 \star tabx2s() and tabs2x() implement the WCS tabular coordinate transformations.
00064 *
00065 * Accuracy:
00066 * --
00067 \star No warranty is given for the accuracy of these routines (refer to the
00068 * copyright notice); intending users must satisfy for themselves their
00069 \star adequacy for the intended purpose. However, closure effectively to within
00070 \star double precision rounding error was demonstrated by test routine ttab.c
00071 \star which accompanies this software.
00072 *
00073 *
00074 * tabini() - Default constructor for the tabprm struct
00076 \star tabini() allocates memory for arrays in a tabprm struct and sets all members
00077 \star of the struct to default values.
00078 *
00079 \star PLEASE NOTE: every tabprm struct should be initialized by tabini(), possibly
00080 \star repeatedly. On the first invokation, and only the first invokation, the 00081 \star flag member of the tabprm struct must be set to -1 to initialize memory
00082 * management, regardless of whether tabini() will actually be used to allocate
00083 * memory.
00084 *
00085 * Given:
00086 *
                    int
                                If true, allocate memory unconditionally for arrays in
          alloc
00087 *
                                the tabprm struct.
00088 *
00089 *
                                If false, it is assumed that pointers to these arrays
00090 *
                                have been set by the user except if they are null
00091 *
                                pointers in which case memory will be allocated for
00092 *
                                them regardless. (In other words, setting alloc true
                                saves having to initalize these pointers to zero.)
00093 *
00094 *
00095 *
                                The number of tabular coordinate axes.
                     int
00096 *
00097 *
          K
                     const int[]
00098 *
                                Vector of length M whose elements (K_1, K_2,... K_M)
00099 *
                                record the lengths of the axes of the coordinate array
00100 *
                                and of each indexing vector. M and K[] are used to
00101 *
                                determine the length of the various tabprm arrays and
00102 *
                                therefore the amount of memory to allocate for them.
00103 *
                                Their values are copied into the tabprm struct.
00104 *
00105 *
                                It is permissible to set K (i.e. the address of the
00106
                                array) to zero which has the same effect as setting
                                each element of K[] to zero. In this case no memory
00107 *
00108 *
                                will be allocated for the index vectors or coordinate
00109 *
                                array in the tabprm struct. These together with the
00110 *
                                K vector must be set separately before calling
00111 *
                                tabset().
```

```
00112 *
00113 \star Given and returned:
00114 *
         tab
                    struct tabprm*
00115 *
                              Tabular transformation parameters. Note that, in
00116 *
                              order to initialize memory management tabprm::flag
                              should be set to -1 when tab is initialized for the
00117 *
                              first time (memory leaks may result if it had already
00118
00119
                              been initialized).
00120 *
00121 * Function return value:
00122 *
                              Status return value:
                    int
00123 *
                                0: Success.
00124 *
                                1: Null tabprm pointer passed.
00125 *
                                2: Memory allocation failed.
00126 *
                                3: Invalid tabular parameters.
00127 *
00128 *
                              For returns > 1, a detailed error message is set in
                              tabprm::err if enabled, see wcserr_enable().
00129 *
00130 *
00131
00132 * tabmem() - Acquire tabular memory
00133 *
00134 \star tabmem() takes control of memory allocated by the user for arrays in the
00135 * tabprm struct.
00136 *
00137 * Given and returned:
00138 *
         tab
00139 *
                              Tabular transformation parameters.
00140 *
00141 * Function return value:
00142 *
                              Status return value:
                   int
00143 *
                                0: Success.
00144 *
                                1: Null tabprm pointer passed.
00145 *
                                2: Memory allocation failed.
00146 *
00147 *
                              For returns > 1, a detailed error message is set in
                              tabprm::err if enabled, see wcserr_enable().
00148 *
00150 *
00151 * tabcpy() - Copy routine for the tabprm struct
00152 *
00153 * tabcpy() does a deep copy of one tabprm struct to another, using tabini() to
00154 * allocate memory for its arrays if required. Only the "information to be
00155 * provided" part of the struct is copied; a call to tabset() is required to
00156 * set up the remainder.
00157 *
00158 * Given:
00159 *
         alloc
                   int
                              If true, allocate memory unconditionally for arrays in
00160 *
                              the tabprm struct.
00161 *
00162 *
                              If false, it is assumed that pointers to these arrays
00163 *
                              have been set by the user except if they are null
00164 *
                              pointers in which case memory will be allocated for
00165 *
                              them regardless. (In other words, setting alloc true
                              saves having to initalize these pointers to zero.)
00166 *
00167 *
         tabsrc const struct tabprm*
00169 *
                              Struct to copy from.
00170 *
00171 * Given and returned:
00172 *
         tabdst struct tabprm*
00173 *
                              Struct to copy to. tabprm::flag should be set to -1
00174 *
                              if tabdst was not previously initialized (memory leaks
00175 *
                              may result if it was previously initialized).
00176 *
00177 * Function return value:

```

```
For example, for tol == 1e-6, all floating-point
00200 *
                                                                              values in the structs must be equal to the first 6
00201 *
                                                                              decimal places. A value of 0 implies exact equality.
00202 *
00203 *
                          tab1
                                                   const struct tabprm*
00204 *
                                                                              The first tabprm struct to compare.
00205 *
00206 *
                         tab2
                                                   const struct tabprm*
00207 *
                                                                             The second tabprm struct to compare.
00208 *
00209 * Returned:
00210 * equal
                                                   int*
                                                                            Non-zero when the given structs are equal.
00211 *
00212 * Function return value:
00213 *
                                                   int
                                                                              Status return value:
00214 *
                                                                                   0: Success.
00215 *
                                                                                   1: Null pointer passed.
00216 *
00218 * tabfree() - Destructor for the tabprm struct
00219 *
00220 \star tabfree() frees memory allocated for the tabprm arrays by tabini().
00221 \star tabini() records the memory it allocates and tabfree() will only attempt to
00222 * free this.
00223 *
00224 * PLEASE NOTE: tabfree() must not be invoked on a tabprm struct that was not
00225 \star initialized by tabini().
00226 *
00227 * Returned:
00228 *
                       tab
                                                   struct tabprm*
00229 *
                                                                             Coordinate transformation parameters.
00230 *
00231 * Function return value:
00232 *
                                                                              Status return value:
                                                   int
00233 *
                                                                                   0: Success.
00234 *
                                                                                   1: Null tabprm pointer passed.
00235 *
00236 *
00237 \star tabsize() - Compute the size of a tabprm struct
00238 *
00239 \star tabsize() computes the full size of a tabprm struct, including allocated
00240 * memory.
00241 *
00242 * Given:
00243 * tab
                                               const struct tabprm*
00244 *
                                                                              Tabular transformation parameters.
00245 *
00246 *
                                                                              If NULL, the base size of the struct and the allocated % \left( 1\right) =\left( 1\right) +\left( 
00247 *
                                                                              size are both set to zero.
00248 *
00249 * Returned:
00250 *
                                                                              The first element is the base size of the struct as
                                                    int[2]
00251 *
                                                                              returned by sizeof(struct tabprm). The second element
                                                                              is the total allocated size, in bytes, assuming that the allocation was done by tabini(). This figure includes memory allocated for the constituent struct,
00252 *

00287 *
00288 *
                                  1: Yes.
00289 *
00290 *
00291 * tabprt() - Print routine for the tabprm struct
00293 \star tabprt() prints the contents of a tabprm struct using wcsprintf(). Mainly
00294 * intended for diagnostic purposes.
00295 *
00296 * Given:
                     const struct tabprm*
00297 * tab
00298 *
                               Tabular transformation parameters.
00299 *
00300 * Function return value:
00301 *
                              Status return value:
                    int
00302 *
                                  0: Success.
00303 *
                                  1: Null tabprm pointer passed.
00304 *
00305
00306 * tabperr() - Print error messages from a tabprm struct
00307 *
00308 * tabperr() prints the error message(s) (if any) stored in a tabprm struct.
00309 \star If there are no errors then nothing is printed. It uses wcserr_prt(), q.v.
00310 *
00311 * Given:
                    const struct tabprm*
00312 *
00313 *
                               Tabular transformation parameters.
00314 *
00315 * prefix
                    const char *
                               If non-NULL, each output line will be prefixed with
00316 *
00317 *
                                this string.
00318 *
00319 * Function return value:
00320 *
                                Status return value:
                     int
00321 *
                                  0: Success.
00322 *
                                  1: Null tabprm pointer passed.
00324 *
00325 \star tabset() - Setup routine for the tabprm struct
00326 *
00327 * tabset() allocates memory for work arrays in the tabprm struct and sets up
00328 \star the struct according to information supplied within it.
00329
00330 \star Note that this routine need not be called directly; it will be invoked by
00331 \star tabx2s() and tabs2x() if tabprm::flag is anything other than a predefined
00332 * magic value.
00333 *
00334 * tabset() normally operates regardless of the value of tabprm::flag; i.e.
00335 * even if a struct was previously set up it will be reset unconditionally.
00336 * However, a tabprm struct may be put into "bypass" mode by invoking tabset()
00337 \star initially with tabprm::flag == 1 (rather than 0). tabset() will return 00338 \star immediately if invoked on a struct in that state. To take a struct out of
00339 \star bypass mode, simply reset tabprm::flag to zero. See also tabenq().
00340 *
00341 * Given and returned:
00342 * tab
                   struct tabprm*
00343 *
                                Tabular transformation parameters.
00344 *
00345 * Function return value:
00346 *
                    int
                               Status return value:
00347 *
                                  0: Success.
00348 *
                                  1: Null tabprm pointer passed.
00349 *
                                  3: Invalid tabular parameters.
00350 *
                                For returns > 1, a detailed error message is set in tabprm::err if enabled, see wcserr_enable().
00351 *
00352 *
00353 *
00354 *
00355 * tabx2s() - Pixel-to-world transformation
00356 *
00357 \star tabx2s() transforms intermediate world coordinates to world coordinates
00358 * using coordinate lookup.
00359 *
00360 * Given and returned:
00361 * tab
                    struct tabprm*
00362 *
                                Tabular transformation parameters.
00363 *
00364 * Given:
00365 *
          ncoord.
00366 *
                               The number of coordinates, each of vector length
          nelem
                    int
00367 *
                               nelem.
00368 *

                                Status return value:
00418 *
                                  0: Success.
00419 *
                                  1: Null tabprm pointer passed.
                                  3: Invalid tabular parameters.
5: One or more of the world coordinates were
00420 *
00421 *
00422 *
                                     invalid, as indicated by the stat vector.
00423
00424 *
                                For returns > 1, a detailed error message is set in
00425 *
                                tabprm::err if enabled, see wcserr_enable().
00426 *
00427 *
00428 * tabprm struct - Tabular transformation parameters
00430 \star The tabprm struct contains information required to transform tabular
00431 \star coordinates. It consists of certain members that must be set by the user
00432 \star ("given") and others that are set by the WCSLIB routines ("returned").
                                                                                     Some
00433 \star of the latter are supplied for informational purposes while others are for
00434 * internal use only.
00435 *
00436 *
00437 *
             (Given and returned) This flag must be set to zero (or 1, see tabset())
00438 *
            whenever any of the following tabp\operatorname{members} are set or changed:
00439 *
              - tabprm::M (q.v., not normally set by the user), - tabprm::K (q.v., not normally set by the user),
00440 *
00441 *
00442 *
              - tabprm::map,
00443 *
              - tabprm::crval,
00444 *
              - tabprm::index,
00445 *
              - tabprm::coord.
00446 *
00447 *
            This signals the initialization routine, tabset(), to recompute the
00448 *
             returned members of the tabprm struct. tabset() will reset flag to
00449 *
             indicate that this has been done.
00450 *
00451 *
            PLEASE NOTE: flag should be set to \neg 1 when tabini() is called for the
00452 *
            first time for a particular tabprm struct in order to initialize memory
00453 *
            \mbox{{\tt management.}} It must \mbox{{\tt ONLY}} be used on the first initialization otherwise
00454 *
            memory leaks may result.
00455 *
00456 *
00457 *
            (Given or returned) Number of tabular coordinate axes.
00458 *
00459 *
            If tabini() is used to initialize the tabprm struct (as would normally
```

```
be the case) then it will set M from the value passed to it as a
            function argument. The user should not subsequently modify it.
00461 *
00462 *
00463 *
          int *K
00464 *
            (Given or returned) Pointer to the first element of a vector of length
            tabprm::M whose elements (K_1, K_2,... K_M) record the lengths of the
00465 *
            axes of the coordinate array and of each indexing vector.
00467 *
            If tabini() is used to initialize the tabprm struct (as would normally
00468 *
            be the case) then it will set K from the array passed to it as a function argument. The user should not subsequently modify it.
00469 *
00470 *
00471 *
00472 *
          int *map
00473 *
            (Given) Pointer to the first element of a vector of length tabprm::M
00474 *
            that defines the association between axis m in the M-dimensional
00475 *
            coordinate array (1 <= m <= M) and the indices of the intermediate world
00476 *
            coordinate and world coordinate arrays, x[] and world[], in the argument
00477 *
            lists for tabx2s() and tabs2x().
00479 *
            When x[] and world[] contain the full complement of coordinate elements
            in image-order, as will usually be the case, then map[m-1] == i-1 for
00480 *
00481 *
            axis i in the N-dimensional image (1 <= i <= N). In terms of the FITS
00482 *
            keywords
00483 *
00484 *
              map[PVi_3a - 1] == i - 1.
00485 *
00486 *
            However, a different association may result if x[], for example, only
00487 *
            contains a (relevant) subset of intermediate world coordinate elements.
00488 *
            For example, if M == 1 for an image with N > 1, it is possible to fill
            x[] with the relevant coordinate element with nelem set to 1. In this
00489 *
00490 *
            case map[0] = 0 regardless of the value of i.
00491 *
00492 *
            (Given) Pointer to the first element of a vector of length tabprm::M
00493 *
00494 *
            whose elements contain the index value for the reference pixel for each
00495
            of the tabular coordinate axes.
00496 *
00497
          double **index
00498 *
            (Given) Pointer to the first element of a vector of length tabprm::M of
00499 *
            pointers to vectors of lengths (K_1, K_2,... K_M) of 0-relative indexes
00500 *
            (see tabprm::K).
00501 *
00502 *
            The address of any or all of these index vectors may be set to zero,
00503 *
            i.e.
00504 *
00505 =
              index[m] == 0;
00506 *
00507 *
            this is interpreted as default indexing, i.e.
00508 *
00509 =
              index[m][k] = k:
00510 *
00511 *
          double *coord
00512 *
            (Given) Pointer to the first element of the tabular coordinate array,
00513 *
            treated as though it were defined as
00514 *
00515 =
              double coord[K M]...[K 2][K 1][M];
00516 *
00517 *
            (see tabprm::K) i.e. with the M dimension varying fastest so that the
00518 *
           M elements of a coordinate vector are stored contiguously in memory.
00519 *
00520 *
          int no
            (Returned) Total number of coordinate vectors in the coordinate array
00521 *
00522 *
            being the product K_1 \star K_2 \star \ldots \star K_M (see tabprm::K).
00523 *
00524 *
          int padding
00525 *
            (An unused variable inserted for alignment purposes only.)
00526 *
00527 *
          int *sense
00528 *
            (Returned) Pointer to the first element of a vector of length tabprm::M
00529 *
            whose elements indicate whether the corresponding indexing vector is
00530 *
            monotonic increasing (+1), or decreasing (-1).
00531 +
00532 *
          int *p0
00533 *
            (Returned) Pointer to the first element of a vector of length tabprm::M
00534 *
            of interpolated indices into the coordinate array such that Upsilon_m,
00535 *
            as defined in Paper III, is equal to (p0[m] + 1) + tabprm::delta[m].
00536 *
00537 *
00538 *
            (Returned) Pointer to the first element of a vector of length tabprm::M
00539 *
            of interpolated indices into the coordinate array such that Upsilon_m,
00540 *
            as defined in Paper III, is equal to (tabprm::p0[m] + 1) + delta[m].
00541
00542 *
00543 *
            (Returned) Pointer to the first element of an array that records the
00544 *
            minimum and maximum value of each element of the coordinate vector in
00545 *
            each row of the coordinate array, treated as though it were defined as
00546 *
```

```
double extrema[K_M]...[K_2][2][M]
00548 *
00549 *
            (see tabprm::K). The minimum is recorded in the first element of the
            compressed K_1 dimension, then the maximum. This array is used by the
00550 *
00551 *
            inverse table lookup function, tabs2x(), to speed up table searches.
00552 *
00553 *
          struct wcserr *err
00554 *
            (Returned) If enabled, when an error status is returned, this struct
00555 *
            contains detailed information about the error, see wcserr_enable().
00556 *
00557 *
          int m_flag
00558 *
           (For internal use only.)
00559 *
          int m_M
00560 *
            (For internal use only.)
00561 *
          int m_N
00562 *
           (For internal use only.)
00563 *
          int set_M
           (For internal use only.)
00564 *
00565 *
          int m_K
00566 *
           (For internal use only.)
00567 *
          int m_map

Data Structures

· struct pvcard

Store for PVi_ma keyrecords.

· struct pscard

Store for PSi_ma keyrecords.

struct auxprm

Additional auxiliary parameters.

· struct wcsprm

Coordinate transformation parameters.

Macros

• #define WCSSUB LONGITUDE 0x1001

Mask for extraction of longitude axis by wcssub().

• #define WCSSUB LATITUDE 0x1002

Mask for extraction of latitude axis by wcssub().

#define WCSSUB CUBEFACE 0x1004

Mask for extraction of CUBEFACE axis by wcssub().

#define WCSSUB CELESTIAL 0x1007

Mask for extraction of celestial axes by wcssub().

• #define WCSSUB_SPECTRAL 0x1008

Mask for extraction of spectral axis by wcssub().

• #define WCSSUB STOKES 0x1010

Mask for extraction of STOKES axis by wcssub().

- #define WCSSUB TIME 0x1020
- #define WCSCOMPARE ANCILLARY 0x0001
- #define WCSCOMPARE_TILING 0x0002
- #define WCSCOMPARE_CRPIX 0x0004
- #define PVLEN (sizeof(struct pvcard)/sizeof(int))
- #define PSLEN (sizeof(struct pscard)/sizeof(int))
- #define AUXLEN (sizeof(struct auxprm)/sizeof(int))
- #define WCSLEN (sizeof(struct wcsprm)/sizeof(int))

Size of the wcsprm struct in int units.

• #define wcscopy(alloc, wcssrc, wcsdst) wcssub(alloc, wcssrc, 0x0, 0x0, wcsdst)

Copy routine for the wcsprm struct.

• #define wcsini_errmsg wcs_errmsg

Deprecated.

#define wcssub_errmsg wcs_errmsg

Deprecated.

• #define wcscopy_errmsg wcs_errmsg

        WCSERR_BAD_SUBIMAGE = 12 , WCSERR_NON_SEPARABLE = 13 , WCSERR_UNSET = 14 }
```

Functions

• int wcsnpv (int n)

Memory allocation for PVi_ma.

• int wcsnps (int n)

Memory allocation for PSi_ma.

int wcsini (int alloc, int naxis, struct wcsprm *wcs)

Default constructor for the wcsprm struct.

int wcsinit (int alloc, int naxis, struct wcsprm *wcs, int npvmax, int npsmax, int ndpmax)

Default constructor for the wcsprm struct.

int wcsauxi (int alloc, struct wcsprm *wcs)

Default constructor for the auxprm struct.

int wcssub (int alloc, const struct wcsprm *wcssrc, int *nsub, int axes[], struct wcsprm *wcsdst)

Subimage extraction routine for the wcsprm struct.

• int wcscompare (int cmp, double tol, const struct wcsprm *wcs1, const struct wcsprm *wcs2, int *equal)

Compare two wcsprm structs for equality.

int wcsfree (struct wcsprm *wcs)

Destructor for the wcsprm struct.

int wcstrim (struct wcsprm *wcs)

Free unused arrays in the wcsprm struct.

• int wcssize (const struct wcsprm *wcs, int sizes[2])

Compute the size of a wcsprm struct.

• int auxsize (const struct auxprm *aux, int sizes[2])

Compute the size of a auxprm struct.

int wcsenq (const struct wcsprm *wcs, int enquiry)

enquire about the state of a wcsprm struct.

int wcsprt (const struct wcsprm *wcs)

Print routine for the wcsprm struct.

int wcsperr (const struct wcsprm *wcs, const char *prefix)

Print error messages from a wcsprm struct.

int wcsbchk (struct wcsprm *wcs, int bounds)

Enable/disable bounds checking.

int wcsset (struct wcsprm *wcs)

Setup routine for the wcsprm struct.

• int wcsp2s (struct wcsprm *wcs, int ncoord, int nelem, const double pixcrd[], double imgcrd[], double phi[], double theta[], double world[], int stat[])

Pixel-to-world transformation.

• int wcss2p (struct wcsprm *wcs, int ncoord, int nelem, const double world[], double phi[], double theta[], double imgcrd[], double pixcrd[], int stat[])

World-to-pixel transformation.

• int wcsmix (struct wcsprm *wcs, int mixpix, int mixcel, const double vspan[2], double vstep, int viter, double world[], double phi[], double theta[], double imgcrd[])

Hybrid coordinate transformation.

• int wcsccs (struct wcsprm *wcs, double lng2p1, double lat2p1, double lng1p2, const char *clng, const char *clat, const char *radesys, double equinox, const char *alt)

Change celestial coordinate system.

int wcssptr (struct wcsprm *wcs, int *i, char ctype[9])

Spectral axis translation.

const char * wcslib_version (int vers[3])

Variables

const char * wcs_errmsg[]
 Status return messages.

6.23.1 Detailed Description

Routines in this suite implement the FITS World Coordinate System (WCS) standard which defines methods to be used for computing world coordinates from image pixel coordinates, and vice versa. The standard, and proposed extensions for handling distortions, are described in

```
"Representations of world coordinates in FITS",
Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061 (WCS Paper I)
"Representations of celestial coordinates in FITS",
Calabretta, M.R., & Greisen, E.W. 2002, A&A, 395, 1077 (WCS Paper II)
"Representations of spectral coordinates in FITS"
Greisen, E.W., Calabretta, M.R., Valdes, F.G., & Allen, S.L. 2006, A&A, 446, 747 (WCS Paper III)
"Representations of distortions in FITS world coordinate systems",
Calabretta, M.R. et al. (WCS Paper IV, draft dated 2004/04/22),
available from http://www.atnf.csiro.au/people/Mark.Calabretta
"Mapping on the HEALPix grid",
Calabretta, M.R., & Roukema, B.F. 2007, MNRAS, 381, 865 (WCS Paper V)
"Representing the 'Butterfly' Projection in FITS -- Projection Code XPH",
Calabretta, M.R., & Lowe, S.R. 2013, PASA, 30, e050 (WCS Paper VI)
"Representations of time coordinates in FITS -
 Time and relative dimension in space",
Rots, A.H., Bunclark, P.S., Calabretta, M.R., Allen, S.L.,
Manchester, R.N., & Thompson, W.T. 2015, A&A, 574, A36 (WCS Paper VII)
```

These routines are based on the wcsprm struct which contains all information needed for the computations. The struct contains some members that must be set by the user, and others that are maintained by these routines, somewhat like a C++ class but with no encapsulation.

wcsnpv(), wcsnps(), wcsinit(), wcssub(), wcsfree(), and wcstrim(), are provided to manage the wcsprm struct, wcssize() computes its total size including allocated memory, wcsenq() returns information about the state of the struct, and wcsprt() prints its contents. wcscopy(), which does a deep copy of one wcsprm struct to another, is defined as a preprocessor macro function that invokes wcssub().

wcsperr() prints the error message(s) (if any) stored in a wcsprm struct, and the linprm, celprm, prjprm, spcprm, and tabprm structs that it contains.

A setup routine, wcsset(), computes intermediate values in the wcsprm struct from parameters in it that were supplied by the user. The struct always needs to be set up by wcsset() but this need not be called explicitly - refer to the explanation of wcsprm::flag.

wcsp2s() and wcss2p() implement the WCS world coordinate transformations. In fact, they are high level driver routines for the WCS linear, logarithmic, celestial, spectral and tabular transformation routines described in lin.h, log.h, cel.h, spc.h and tab.h.

Given either the celestial longitude or latitude plus an element of the pixel coordinate a hybrid routine, wcsmix(), iteratively solves for the unknown elements.

wcsccs() changes the celestial coordinate system of a wcsprm struct, for example, from equatorial to galactic, and wcssptr() translates the spectral axis. For example, a 'FREQ' axis may be translated into 'ZOPT-F2W' and vice versa.

wcslib_version() returns the WCSLIB version number.

Quadcube projections:

The quadcube projections (TSC, CSC, QSC) may be represented in FITS in either of two ways:

a: The six faces may be laid out in one plane and numbered as follows:

```
4 3 2 1 4 3 2
```

Faces 2, 3 and 4 may appear on one side or the other (or both). The world-to-pixel routines map faces 2, 3 and 4 to the left but the pixel-to-world routines accept them on either side.

b: The "COBE" convention in which the six faces are stored in a three-dimensional structure using a **CUBEFACE** axis indexed from 0 to 5 as above.

These routines support both methods; wcsset() determines which is being used by the presence or absence of a CUBEFACE axis in ctype[]. wcsp2s() and wcss2p() translate the CUBEFACE axis representation to the single plane representation understood by the lower-level WCSLIB projection routines.

6.23.2 Macro Definition Documentation

WCSSUB LONGITUDE

```
#define WCSSUB_LONGITUDE 0x1001
```

Mask for extraction of longitude axis by wcssub().

Mask to use for extracting the longitude axis when sub-imaging, refer to the axes argument of wcssub().

WCSSUB LATITUDE

```
#define WCSSUB_LATITUDE 0x1002
```

Mask for extraction of latitude axis by wcssub().

Mask to use for extracting the latitude axis when sub-imaging, refer to the axes argument of wcssub().

WCSSUB CUBEFACE

```
#define WCSSUB CUBEFACE 0x1004
```

Mask for extraction of CUBEFACE axis by wcssub().

Mask to use for extracting the CUBEFACE axis when sub-imaging, refer to the axes argument of wcssub().

WCSSUB_CELESTIAL

#define WCSSUB_CELESTIAL 0x1007

Mask for extraction of celestial axes by wcssub().

Mask to use for extracting the celestial axes (longitude, latitude and cubeface) when sub-imaging, refer to the axes argument of wcssub().

WCSSUB_SPECTRAL

#define WCSSUB_SPECTRAL 0x1008

Mask for extraction of spectral axis by wcssub().

Mask to use for extracting the spectral axis when sub-imaging, refer to the axes argument of wcssub().

WCSSUB_STOKES

#define WCSSUB_STOKES 0x1010

Mask for extraction of STOKES axis by wcssub().

Mask to use for extracting the STOKES axis when sub-imaging, refer to the axes argument of wcssub().

WCSSUB_TIME

#define WCSSUB_TIME 0x1020

WCSCOMPARE_ANCILLARY

#define WCSCOMPARE_ANCILLARY 0x0001

WCSCOMPARE_TILING

#define WCSCOMPARE_TILING 0x0002

WCSCOMPARE_CRPIX

#define WCSCOMPARE_CRPIX 0x0004

PVLEN

#define PVLEN (sizeof(struct pvcard)/sizeof(int))

PSLEN

```
#define PSLEN (sizeof(struct pscard)/sizeof(int))
```

AUXLEN

```
#define AUXLEN (sizeof(struct auxprm)/sizeof(int))
```

WCSLEN

```
#define WCSLEN (sizeof(struct wcsprm)/sizeof(int))
```

Size of the wcsprm struct in int units.

Size of the wcsprm struct in *int* units, used by the Fortran wrappers.

wcscopy

Copy routine for the wcsprm struct.

wcscopy() does a deep copy of one wcsprm struct to another. As of WCSLIB 3.6, it is implemented as a preprocessor macro that invokes wcssub() with the nsub and axes pointers both set to zero.

wcsini_errmsg

```
#define wcsini_errmsg wcs_errmsg
```

Deprecated.

Deprecated Added for backwards compatibility, use wcs_errmsg directly now instead.

wcssub_errmsg

```
#define wcssub_errmsg wcs_errmsg
```

Deprecated.

Deprecated Added for backwards compatibility, use wcs_errmsg directly now instead.

wcscopy_errmsg

#define wcscopy_errmsg wcs_errmsg

Deprecated.

Deprecated Added for backwards compatibility, use wcs_errmsg directly now instead.

wcsfree_errmsg

#define wcsfree_errmsg wcs_errmsg

Deprecated.

Deprecated Added for backwards compatibility, use wcs_errmsg directly now instead.

wcsprt_errmsg

#define wcsprt_errmsg wcs_errmsg

Deprecated.

Deprecated Added for backwards compatibility, use wcs_errmsg directly now instead.

wcsset_errmsg

#define wcsset_errmsg wcs_errmsg

Deprecated.

Deprecated Added for backwards compatibility, use wcs_errmsg directly now instead.

wcsp2s_errmsg

#define wcsp2s_errmsg wcs_errmsg

Deprecated.

Deprecated Added for backwards compatibility, use wcs_errmsg directly now instead.

wcss2p_errmsg

#define wcss2p_errmsg wcs_errmsg

Deprecated.

Deprecated Added for backwards compatibility, use wcs_errmsg directly now instead.

wcsmix_errmsg

#define wcsmix_errmsg wcs_errmsg

Deprecated.

Deprecated Added for backwards compatibility, use wcs_errmsg directly now instead.

6.23.4 Function Documentation

wcsnpv()

Memory allocation for **PV**i_ma.

wcsnpv() sets or gets the value of NPVMAX (default 64). This global variable controls the number of pvcard structs, for holding **PV**i_ma keyvalues, that wcsini() should allocate space for. It is also used by wcsinit() as the default value of npvmax.

PLEASE NOTE: This function is not thread-safe.

Parameters

in	n	Value of NPVMAX; ignored if $<$ 0. Use a value less than zero to get the current value.
----	---	---

Returns

Current value of NPVMAX.

wcsnps()

```
int wcsnps ( \quad \text{int } n \ )
```

Memory allocation for **PS**i_ma.

wcsnps() sets or gets the value of NPSMAX (default 8). This global variable controls the number of pscard structs, for holding PSi_ma keyvalues, that wcsini() should allocate space for. It is also used by wcsinit() as the default value of npsmax.

PLEASE NOTE: This function is not thread-safe.

Parameters

in n Value of NPSMAX; ignored if $<$ 0. Use a value less than zero to get the current value.
--

Returns

Current value of NPSMAX.

wcsini()

```
int wcsini (
                int alloc,
                int naxis,
                struct wcsprm * wcs )
```

Default constructor for the wcsprm struct.

wcsini() is a thin wrapper on wcsinit(). It invokes it with npvmax, npsmax, and ndpmax set to -1 which causes it to use the values of the global variables NDPMAX, NPSMAX, and NDPMAX. It is thereby potentially thread-unsafe if these variables are altered dynamically via wcsnpv(), wcsnps(), and disndp(). Use wcsinit() for a thread-safe alternative in this case.

wcsinit()

```
int wcsinit (
    int alloc,
    int naxis,
    struct wcsprm * wcs,
    int npvmax,
    int npsmax,
    int ndpmax )
```

Default constructor for the wcsprm struct.

wcsinit() optionally allocates memory for arrays in a wcsprm struct and sets all members of the struct to default values.

PLEASE NOTE: every wcsprm struct should be initialized by **wcsinit**(), possibly repeatedly. On the first invokation, and only the first invokation, wcsprm::flag must be set to -1 to initialize memory management, regardless of whether **wcsinit**() will actually be used to allocate memory.

Parameters

in	alloc	If true, allocate memory unconditionally for the crpix, etc. arrays. Please note that memory is never allocated by wcsinit () for the auxprm, tabprm, nor wtbarr structs. If false, it is assumed that pointers to these arrays have been set by the user except if they are null pointers in which case memory will be allocated for them regardless. (In other words, setting alloc true saves having to initalize these pointers to zero.)
in	naxis	The number of world coordinate axes. This is used to determine the length of the various wcsprm vectors and matrices and therefore the amount of memory to allocate for them.
in,out	wcs	Coordinate transformation parameters. Note that, in order to initialize memory management, wcsprm::flag should be set to -1 when wcs is initialized for the first time (memory leaks may result if it had already been initialized).
in	npvmax	The number of PV i_ma keywords to allocate space for. If set to -1, the value of the global variable NPVMAX will be used. This is potentially thread-unsafe if wcsnpv() is being used dynamically to alter its value.
in	npsmax	The number of PSi_ma keywords to allocate space for. If set to -1, the value of the global variable NPSMAX will be used. This is potentially thread-unsafe if wesnps() is
Generated on Tue	May 14 2024 02	and the state of t
in	ndpmax	The number of DPja or DQia keywords to allocate space for. If set to -1, the value of the global variable NDPMAX will be used. This is potentially thread-unsafe if disndp() is being used dynamically to alter its value.

Returns

Status return value:

- 0: Success.
- 1: Null wcsprm pointer passed.
- 2: Memory allocation failed.

For returns > 1, a detailed error message is set in wcsprm::err if enabled, see wcserr_enable().

wcsauxi()

```
int wcsauxi (
                int alloc,
                struct wcsprm * wcs )
```

Default constructor for the auxprm struct.

wcsauxi() optionally allocates memory for an auxprm struct, attaches it to wcsprm, and sets all members of the struct to default values.

Parameters

in	alloc	If true, allocate memory unconditionally for the auxprm struct. If false, it is assumed that wcsprm::aux has already been set to point to an auxprm struct, in which case the user is responsible for managing that memory. However, if wcsprm::aux is a null pointer, memory will be allocated regardless. (In other words, setting alloc true saves having to initalize the pointer to zero.)
in,out	wcs	Coordinate transformation parameters.

Returns

Status return value:

- 0: Success.
- 1: Null wcsprm pointer passed.
- 2: Memory allocation failed.

wcssub()

Subimage extraction routine for the wcsprm struct.

wcssub() extracts the coordinate description for a subimage from a wcsprm struct. It does a deep copy, using wcsinit() to allocate memory for its arrays if required. Only the "information to be provided" part of the struct is

extracted. Consequently, wcsset() need not have been, and won't be invoked on the struct from which the subimage is extracted. A call to wcsset() is required to set up the subimage struct.

The world coordinate system of the subimage must be separable in the sense that the world coordinates at any point in the subimage must depend only on the pixel coordinates of the axes extracted. In practice, this means that the linear transformation matrix of the original image must not contain non-zero off-diagonal terms that associate any of the subimage axes with any of the non-subimage axes. Likewise, if any distortions are associated with the subimage axes, they must not depend on any of the axes that are not being extracted.

Note that while the required elements of the tabprm array are extracted, the wtbarr array is not. (Thus it is not appropriate to call **wcssub**() after wcstab() but before filling the tabprm structs - refer to wcshdr.h.)

wcssub() can also add axes to a wcsprm struct. The new axes will be created using the defaults set by wcsinit() which produce a simple, unnamed, linear axis with world coordinate equal to the pixel coordinate. These default values can be changed afterwards, before invoking wcsset().

Parameters

in	alloc	If true, allocate memory for the crpix, etc. arrays in the destination. Otherwise, it is
TII	alloc	assumed that pointers to these arrays have been set by the user except if they are null
		pointers in which case memory will be allocated for them regardless.
in	wcssrc	Struct to extract from.
in,out	nsub	
in, out	axes	Vector of length *nsub containing the image axis numbers (1-relative) to extract. Order is significant; axes[0] is the axis number of the input image that corresponds to the first axis in the subimage, etc. Use an axis number of 0 to create a new axis using the defaults set by wcsinit(). They can be changed later. nsub (the pointer) may be set to zero, and so also may *nsub, which is interpreted to mean all axes in the input image; the number of axes will be returned if nsub!= 0x0. axes itself (the pointer) may be set to zero to indicate the first *nsub axes in their original order. Set both nsub (or *nsub) and axes to zero to do a deep copy of one wcsprm struct to another. Subimage extraction by coordinate axis type may be done by setting the elements of axes[] to the following special preprocessor macro values:
		WCSSUB_LONGITUDE: Celestial longitude. WCSSUB_LATITUDE: Celestial latitude.
		 WCSSUB_CUBEFACE: Quadcube CUBEFACE axis.
		WCSSUB_SPECTRAL: Spectral axis.
		WCSSUB_STOKES: Stokes axis.
		WCSSUB_TIME: Time axis.
		Refer to the notes (below) for further usage examples. On return, *nsub will be set to the number of axes in the subimage; this may be zero if there were no axes of the required type(s) (in which case no memory will be allocated). axes[] will contain the axis numbers that were extracted, or 0 for newly created axes. The vector length must be sufficient to contain all axis numbers. No checks are performed to verify that the coordinate axes are consistent, this is done by wcsset().
in,out	wcsdst	Struct describing the subimage. wcsprm::flag should be set to -1 if wcsdst was not previously initialized (memory leaks may result if it was previously initialized).

Returns

Status return value:

- 0: Success.
- · 1: Null wcsprm pointer passed.
- · 2: Memory allocation failed.
- · 12: Invalid subimage specification.
- 13: Non-separable subimage coordinate system.

For returns > 1, a detailed error message is set in wcsprm::err if enabled, see wcserr enable().

Notes:

1. Combinations of subimage axes of particular types may be extracted in the same order as they occur in the input image by combining preprocessor codes, for example

```
*nsub = 1;
axes[0] = WCSSUB_LONGITUDE | WCSSUB_LATITUDE | WCSSUB_SPECTRAL;
```

would extract the longitude, latitude, and spectral axes in the same order as the input image. If one of each were present, *nsub = 3 would be returned.

For convenience, WCSSUB_CELESTIAL is defined as the combination WCSSUB_LONGITUDE | WCSSUB_LATITUDE | WCSSUB_CUBEFACE.

The codes may also be negated to extract all but the types specified, for example

```
*nsub = 4;
axes[0] = WCSSUB_LONGITUDE;
axes[1] = WCSSUB_LATITUDE;
axes[2] = WCSSUB_CUBEFACE;
axes[3] = -(WCSSUB_SPECTRAL | WCSSUB_STOKES);
```

The last of these specifies all axis types other than spectral or Stokes. Extraction is done in the order specified by axes[] a longitude axis (if present) would be extracted first (via axes[0]) and not subsequently (via axes[3]). Likewise for the latitude and cubeface axes in this example.

From the foregoing, it is apparent that the value of *nsub returned may be less than or greater than that given. However, it will never exceed the number of axes in the input image (plus the number of newly-created axes if any were specified on input).

wcscompare()

```
int wcscompare (
    int cmp,
    double tol,
    const struct wcsprm * wcs1,
    const struct wcsprm * wcs2,
    int * equal )
```

Compare two wcsprm structs for equality.

wcscompare() compares two wcsprm structs for equality.

Parameters

in	стр	A bit field controlling the strictness of the comparison. When 0, all fields must be identical. The following constants may be or'ed together to relax the comparison:
		 WCSCOMPARE_ANCILLARY: Ignore ancillary keywords that don't change the WCS transformation, such as DATE-OBS or EQUINOX.
		 WCSCOMPARE_TILING: Ignore integral differences in CRPIXja. This is the 'tiling' condition, where two WCSes cover different regions of the same map projection and align on the same map grid.
		 WCSCOMPARE_CRPIX: Ignore any differences at all in CRPIXja. The two WCSes cover different regions of the same map projection but may not align on the same map grid. Overrides WCSCOMPARE_TILING.
in	tol	Tolerance for comparison of floating-point values. For example, for tol == 1e-6, all
		floating-point values in the structs must be equal to the first 6 decimal places. A value of 0
		implies exact equality.
in	wcs1	The first wcsprm struct to compare.
in	wcs2	The second wcsprm struct to compare.
out	equal	Non-zero when the given structs are equal.

Returns

Status return value:

- 0: Success.
- 1: Null pointer passed.

wcsfree()

Destructor for the wcsprm struct.

wcsfree() frees memory allocated for the wcsprm arrays by wcsinit() and/or wcsset(). wcsinit() records the memory it allocates and wcsfree() will only attempt to free this.

PLEASE NOTE: wcsfree() must not be invoked on a wcsprm struct that was not initialized by wcsinit().

Parameters

in,out	wcs	Coordinate transformation parameters.
--------	-----	---------------------------------------

Returns

Status return value:

- 0: Success.
- 1: Null wcsprm pointer passed.

wcstrim()

```
int wcstrim ( {\tt struct\ wcsprm\ *\ wcs\ )}
```

Free unused arrays in the wcsprm struct.

wcstrim() frees memory allocated by wcsinit() for arrays in the wcsprm struct that remains unused after it has been set up by wcsset().

The free'd array members are associated with FITS WCS keyrecords that are rarely used and usually just bloat the struct: wcsprm::crota, wcsprm::colax, wcsprm::cname, wcsprm::crder, wcsprm::csyer, wcsprm::czphs, and wcsprm::cperi. If unused, wcsprm::pv, wcsprm::ps, and wcsprm::cd are also freed.

Once these arrays have been freed, a test such as

```
if (!undefined(wcs->cname[i])) {...}
```

must be protected as follows

```
if (wcs->cname && !undefined(wcs->cname[i])) {...}
```

In addition, if wcsprm::npv is non-zero but less than wcsprm::npvmax, then the unused space in wcsprm::pv will be recovered (using realloc()). Likewise for wcsprm::ps.

Parameters

-	in,out	wcs	Coordinate transformation parameters.	1
---	--------	-----	---------------------------------------	---

Returns

Status return value:

- 0: Success.
- 1: Null wcsprm pointer passed.
- 14: wcsprm struct is unset.

wcssize()

Compute the size of a wcsprm struct.

wcssize() computes the full size of a wcsprm struct, including allocated memory.

Parameters

in	wcs	Coordinate transformation parameters. If NULL, the base size of the struct and the allocated size are both set to zero.
out	sizes	The first element is the base size of the struct as returned by sizeof(struct wcsprm). The second element is the total allocated size, in bytes, assuming that the allocation was done by wcsini(). This figure includes memory allocated for members of constituent structs, such as wcsprm::lin. It is not an error for the struct not to have been set up via wcsset(), which normally results in additional memory allocation.

Returns

Status return value:

• 0: Success.

auxsize()

Compute the size of a auxprm struct.

auxsize() computes the full size of an auxprm struct, including allocated memory.

Parameters

in	aux	Auxiliary coordinate information. If NULL, the base size of the struct and the allocated size are both set to zero.	
out	sizes	The first element is the base size of the struct as returned by sizeof(struct auxprm). The second element is the total allocated size, in bytes, currently zero.	

Returns

Status return value:

• 0: Success.

wcsenq()

enquire about the state of a wcsprm struct.

wcsenq() may be used to obtain information about the state of a wcsprm struct. The function returns a true/false answer for the enquiry asked.

Parameters

in	wcs	Coordinate transformation parameters.
in	enquiry	Enquiry according to the following parameters:
		WCSENQ_MEM: memory in the struct is being managed by WCSLIB (see wcsini()).
		 WCSENQ_SET: the struct has been set up by wcsset().
		 WCSENQ_BYP: the struct is in bypass mode (see wcsset()).
		 WCSENQ_CHK: the struct is self-consistent in that no changes have been made to any of the "parameters to be given" since the last call to wcsset().
		These may be combined by logical OR, e.g. WCSENQ_MEM WCSENQ_SET. The enquiry result will be the logical AND of the individual results.

Returns

Enquiry result:

- 0: False.
- 1: True.

wcsprt()

```
int wcsprt ( {\tt const\ struct\ wcsprm\ *\ wcs\ )}
```

Print routine for the wcsprm struct.

wcsprt() prints the contents of a wcsprm struct using wcsprintf(). Mainly intended for diagnostic purposes.

Parameters

	in <i>wcs</i>	Coordinate transformation parameters.	1
--	---------------	---------------------------------------	---

Returns

Status return value:

- 0: Success.
- 1: Null wcsprm pointer passed.

wcsperr()

Print error messages from a wcsprm struct.

wcsperr() prints the error message(s), if any, stored in a wcsprm struct, and the linprm, celprm, prjprm, spcprm, and tabprm structs that it contains. If there are no errors then nothing is printed. It uses wcserr_prt(), q.v.

Parameters

in	wcs	Coordinate transformation parameters.
in	prefix	If non-NULL, each output line will be prefixed with this string.

Returns

Status return value:

- 0: Success.
- 1: Null wcsprm pointer passed.

6.23 wcs.h File Reference 321

wcsbchk()

Enable/disable bounds checking.

wcsbchk() is used to control bounds checking in the projection routines. Note that wcsset() always enables bounds checking. **wcsbchk**() will invoke wcsset() on the wcsprm struct beforehand if necessary.

Parameters

in,out	wcs	Coordinate transformation parameters.
in	bounds	If bounds&1 then enable strict bounds checking for the spherical-to-Cartesian (s2x) transformation for the AZP, SZP, TAN, SIN, ZPN, and COP projections. If bounds&2 then enable strict bounds checking for the Cartesian-to-spherical (x2s) transformation for the HPX and XPH projections. If bounds&4 then enable bounds checking on the native coordinates returned by the Cartesian-to-spherical (x2s) transformations using prjchk(). Zero it to disable all checking.

Returns

Status return value:

- 0: Success.
- · 1: Null wcsprm pointer passed.

wcsset()

```
int wcsset ( {\tt struct\ wcsprm\ *\ wcs\ )}
```

Setup routine for the wcsprm struct.

wcsset() sets up a wcsprm struct according to information supplied within it (refer to the description of the wcsprm struct).

wcsset() recognizes the NCP projection and converts it to the equivalent SIN projection and likewise translates GLS into SFL. It also translates the AIPS spectral types ('FREQ-LSR', 'FELO-HEL', etc.), possibly changing the input header keywords wcsprm::ctype and/or wcsprm::specsys if necessary.

Note that this routine need not be called directly; it will be invoked by wcsp2s() and wcss2p() if the wcsprm::flag is anything other than a predefined magic value.

wcsset() normally operates regardless of the value of wcsprm::flag; i.e. even if a struct was previously set up it will be reset unconditionally. However, a wcsprm struct may be put into "bypass" mode by invoking wcsset() initially with wcsprm::flag == 1 (rather than 0). wcsset() will return immediately if invoked on a struct in that state. To take a struct out of bypass mode, simply reset wcsprm::flag to zero. See also wcsenq().

in,out	wcs	Coordinate transformation parameters.
--------	-----	---------------------------------------

Returns

Status return value:

- 0: Success.
- 1: Null wcsprm pointer passed.
- 2: Memory allocation failed.
- 3: Linear transformation matrix is singular.
- 4: Inconsistent or unrecognized coordinate axis types.
- 5: Invalid parameter value.
- 6: Invalid coordinate transformation parameters.
- 7: Ill-conditioned coordinate transformation parameters.

For returns > 1, a detailed error message is set in wcsprm::err if enabled, see wcserr_enable().

Notes:

1. **wcsset**() always enables strict bounds checking in the projection routines (via a call to prjini()). Use wcsbchk() to modify bounds-checking after wcsset() is invoked.

wcsp2s()

Pixel-to-world transformation.

wcsp2s() transforms pixel coordinates to world coordinates.

in,out	wcs	Coordinate transformation parameters.
in	ncoord,nelem	The number of coordinates, each of vector length nelem but containing wcs.naxis coordinate elements. Thus nelem must equal or exceed the value of the NAXIS keyword unless ncoord == 1, in which case nelem is not used.
in	pixcrd	Array of pixel coordinates.
out	imgcrd	Array of intermediate world coordinates. For celestial axes, imgcrd[][wcs.lng] and imgcrd[][wcs.lat] are the projected x -, and y -coordinates in pseudo "degrees". For spectral axes, imgcrd[][wcs.spec] is the intermediate spectral coordinate, in SI units. For time axes, imgcrd[][wcs.time] is the intermediate time coordinate.
out	phi,theta	Longitude and latitude in the native coordinate system of the projection [deg].
out	world	Array of world coordinates. For celestial axes, world[][wcs.lng] and world[][wcs.lat] are the celestial longitude and latitude [deg]. For spectral axes, world[][wcs.spec] is the spectral coordinate, in SI units. For time axes, world[][wcs.time] is the time coordinate.
out	stat	Status return value for each coordinate element(s) Status return value for each coordinate element(s)

6.23 wcs.h File Reference 323

Returns

Status return value:

- 0: Success.
- 1: Null wcsprm pointer passed.
- 2: Memory allocation failed.
- 3: Linear transformation matrix is singular.
- 4: Inconsistent or unrecognized coordinate axis types.
- 5: Invalid parameter value.
- 6: Invalid coordinate transformation parameters.
- 7: Ill-conditioned coordinate transformation parameters.
- 8: One or more of the pixel coordinates were invalid, as indicated by the stat vector.

For returns > 1, a detailed error message is set in wcsprm::err if enabled, see wcserr_enable().

wcss2p()

World-to-pixel transformation.

wcss2p() transforms world coordinates to pixel coordinates.

in,out	wcs	Coordinate transformation parameters.
in	ncoord,nelem	The number of coordinates, each of vector length nelem but containing wcs.naxis coordinate elements. Thus nelem must equal or exceed the value of the NAXIS keyword unless ncoord == 1, in which case nelem is not used.
in	world	Array of world coordinates. For celestial axes, world[][wcs.lng] and world[][wcs.lat] are the celestial longitude and latitude [deg]. For spectral axes, world[][wcs.spec] is the spectral coordinate, in SI units. For time axes, world[][wcs.time] is the time coordinate.
out	phi,theta	Longitude and latitude in the native coordinate system of the projection [deg].
out	imgcrd	Array of intermediate world coordinates. For celestial axes, imgcrd[][wcs.lng] and imgcrd[][wcs.lat] are the projected x -, and y -coordinates in pseudo "degrees". For quadcube projections with a CUBEFACE axis the face number is also returned in imgcrd[][wcs.cubeface]. For spectral axes, imgcrd[][wcs.spec] is the intermediate spectral coordinate, in SI units. For time axes, imgcrd[][wcs.time] is the intermediate time coordinate.
out	pixcrd	Array of pixel coordinates.
out	stat	Status return value for each coordinate: • 0: Success.
		1+: A bit mask indicating invalid world coordinate element(s).

Returns

Status return value:

- · 0: Success.
- 1: Null wcsprm pointer passed.
- 2: Memory allocation failed.
- 3: Linear transformation matrix is singular.
- 4: Inconsistent or unrecognized coordinate axis types.
- 5: Invalid parameter value.
- 6: Invalid coordinate transformation parameters.
- 7: Ill-conditioned coordinate transformation parameters.
- 9: One or more of the world coordinates were invalid, as indicated by the stat vector.

For returns > 1, a detailed error message is set in wcsprm::err if enabled, see wcserr_enable().

wcsmix()

Hybrid coordinate transformation.

wcsmix(), given either the celestial longitude or latitude plus an element of the pixel coordinate, solves for the remaining elements by iterating on the unknown celestial coordinate element using wcss2p(). Refer also to the notes below.

in,out	in, out wcs Indices for the celestial coordinates obtained by parsing the wcsprm::ctype[].	
in	in mixpix Which element of the pixel coordinate is given.	
in	mixcel	Which element of the celestial coordinate is given:
		 1: Celestial longitude is given in world[wcs.lng], latitude returned in world[wcs.lat].
		 2: Celestial latitude is given in world[wcs.lat], longitude returned in world[wcs.lng].
in	vspan	Solution interval for the celestial coordinate [deg]. The ordering of the two limits is irrelevant. Longitude ranges may be specified with any convenient normalization, for example [-120,+120] is the same as [240,480], except that the solution will be returned with the same normalization, i.e. lie within the interval specified.
in	vstep	Step size for solution search [deg]. If zero, a sensible, although perhaps non-optimal default will be used.

6.23 wcs.h File Reference 325

Parameters

in	viter	If a solution is not found then the step size will be halved and the search recommenced. viter controls how many times the step size is halved. The allowed range is 5 - 10.
in,out	world	World coordinate elements. world[wcs.lng] and world[wcs.lat] are the celestial longitude and latitude [deg]. Which is given and which returned depends on the value of mixcel. All other elements are given.
out	phi,theta	Longitude and latitude in the native coordinate system of the projection [deg].
out	imgcrd	Image coordinate elements. imgcrd[wcs.lng] and imgcrd[wcs.lat] are the projected x -, and y -coordinates in pseudo "degrees".
in,out	pixcrd	Pixel coordinate. The element indicated by mixpix is given and the remaining elements are returned.

Returns

Status return value:

- · 0: Success.
- 1: Null wcsprm pointer passed.
- · 2: Memory allocation failed.
- · 3: Linear transformation matrix is singular.
- 4: Inconsistent or unrecognized coordinate axis types.
- 5: Invalid parameter value.
- 6: Invalid coordinate transformation parameters.
- 7: Ill-conditioned coordinate transformation parameters.
- 10: Invalid world coordinate.
- 11: No solution found in the specified interval.

For returns > 1, a detailed error message is set in wcsprm::err if enabled, see wcserr enable().

Notes:

1. Initially the specified solution interval is checked to see if it's a "crossing" interval. If it isn't, a search is made for a crossing solution by iterating on the unknown celestial coordinate starting at the upper limit of the solution interval and decrementing by the specified step size. A crossing is indicated if the trial value of the pixel coordinate steps through the value specified. If a crossing interval is found then the solution is determined by a modified form of "regula falsi" division of the crossing interval. If no crossing interval was found within the specified solution interval then a search is made for a "non-crossing" solution as may arise from a point of tangency. The process is complicated by having to make allowance for the discontinuities that occur in all map projections.

Once one solution has been determined others may be found by subsequent invokations of **wcsmix**() with suitably restricted solution intervals.

Note the circumstance that arises when the solution point lies at a native pole of a projection in which the pole is represented as a finite curve, for example the zenithals and conics. In such cases two or more valid solutions may exist but **wcsmix**() only ever returns one.

Because of its generality **wcsmix**() is very compute-intensive. For compute-limited applications more efficient special-case solvers could be written for simple projections, for example non-oblique cylindrical projections.

wcsccs()

Change celestial coordinate system.

wcsccs() changes the celestial coordinate system of a wcsprm struct. For example, from equatorial to galactic coordinates.

Parameters that define the spherical coordinate transformation, essentially being three Euler angles, must be provided. Thereby **wcsccs**() does not need prior knowledge of specific celestial coordinate systems. It also has the advantage of making it completely general.

Auxiliary members of the wcsprm struct relating to equatorial celestial coordinate systems may also be changed.

Only orthodox spherical coordinate systems are supported. That is, they must be right-handed, with latitude increasing from zero at the equator to +90 degrees at the pole. This precludes systems such as aziumuth and zenith distance, which, however, could be handled as negative azimuth and elevation.

PLEASE NOTE: Information in the wcsprm struct relating to the original coordinate system will be overwritten and therefore lost. If this is undesirable, invoke **wcsccs**() on a copy of the struct made with wcssub(). The wcsprm struct is reset on return with an explicit call to wcsset().

in,out	wcs	Coordinate transformation parameters. Particular "values to be given" elements of the wcsprm struct are modified.
in	lng2p1,lat2p1	Longitude and latitude in the new celestial coordinate system of the pole (i.e. latitude +90) of the original system [deg]. See notes 1 and 2 below.
in	Ing1p2	Longitude in the original celestial coordinate system of the pole (i.e. latitude +90) of the new system [deg]. See note 1 below.
in	clng,clat	Longitude and latitude identifiers of the new CTYPEia celestial axis codes, without trailing dashes. For example, "RA" and "DEC" or "GLON" and "GLAT". Up to four characters are used, longer strings need not be null-terminated.
in	radesys	Used when transforming to equatorial coordinates, identified by clng == "RA" and clat = "DEC". May be set to the null pointer to preserve the current value. Up to 71 characters are used, longer strings need not be null-terminated. If the new coordinate system is anything other than equatorial, then wcsprm::radesys will be cleared.
in	equinox	Used when transforming to equatorial coordinates. May be set to zero to preserve the current value. If the new coordinate system is not equatorial, then wcsprm::equinox will be marked as undefined.
in	alt	Character code for alternate coordinate descriptions (i.e. the 'a' in keyword names such as CTYPEia). This is blank for the primary coordinate description, or one of the 26 upper-case letters, A-Z. May be set to the null pointer, or null string if no change is required.

6.23 wcs.h File Reference 327

Returns

Status return value:

- · 0: Success.
- 1: Null wcsprm pointer passed.
- 12: Invalid subimage specification (no celestial axes).

Notes:

- 1. Follows the prescription given in WCS Paper II, Sect. 2.7 for changing celestial coordinates.
 - The implementation takes account of indeterminacies that arise in that prescription in the particular cases where one of the poles of the new system is at the fiducial point, or one of them is at the native pole.
- 2. If lat2p1 == +90, i.e. where the poles of the two coordinate systems coincide, then the spherical coordinate transformation becomes a simple change in origin of longitude given by lng2 = lng1 + (lng2p1 lng1p2 180), and lat2 = lat1, where (lng2,lat2) are coordinates in the new system, and (lng1,lat1) are coordinates in the original system.

```
Likewise, if lat2p1 == -90, then lng2 = -lng1 + (lng2p1 + lng1p2), and lat2 = -lat1.
```

- 3. For example, if the original coordinate system is B1950 equatorial and the desired new coordinate system is galactic, then

 - (clng,clat) would be 'GLON' and 'GLAT', these being the FITS standard identifiers for galactic coordinates.
 - Since the new coordinate system is not equatorial, wcsprm::radesys and wcsprm::equinox will be cleared.
- 4. The coordinates required for some common transformations (obtained from https://ned.ipac.
 caltech.edu/coordinate_calculator) are as follows:

```
(123.0000,+27.4000) galactic coordinates of B1950 celestial pole, (192.2500,+27.4000) B1950 equatorial coordinates of galactic pole. (122.9319,+27.1283) galactic coordinates of J2000 celestial pole, (192.8595,+27.1283) J2000 equatorial coordinates of galactic pole. (359.6774,+89.7217) B1950 equatorial coordinates of J2000 pole, (180.3162,+89.7217) J2000 equatorial coordinates of B1950 pole. (270.0000,+66.5542) B1950 equatorial coordinates of B1950 ecliptic pole, (90.0000,+66.5542) B1950 ecliptic coordinates of B1950 celestial pole. (270.0000,+66.5607) J2000 equatorial coordinates of J2000 ecliptic pole, (90.0000,+66.5607) J2000 ecliptic coordinates of J2000 ecliptic pole, (26.7315,+15.6441) supergalactic coordinates of B1950 celestial pole, (283.1894,+15.6441) B1950 equatorial coordinates of supergalactic pole, (26.4505,+15.7089) supergalactic coordinates of J2000 celestial pole, (283.7542,+15.7089) J2000 equatorial coordinates of supergalactic pole.
```

wcssptr()

```
int wcssptr (
          struct wcsprm * wcs,
          int * i,
          char ctype[9] )
```

Spectral axis translation.

wcssptr() translates the spectral axis in a wcsprm struct. For example, a 'FREQ' axis may be translated into 'ZOPT-F2W' and vice versa.

PLEASE NOTE: Information in the wcsprm struct relating to the original coordinate system will be overwritten and therefore lost. If this is undesirable, invoke **wcssptr**() on a copy of the struct made with wcssub(). The wcsprm struct is reset on return with an explicit call to wcsset().

Parameters

in,out	wcs	Coordinate transformation parameters.
in,out	Index of the spectral axis (0-relative). If given < 0 it will be set to the first specified identified from the ctype[] keyvalues in the wcsprm struct.	
		identified from the ctype[] keyvalues in the wesprin struct.
in,out	ctype	Desired spectral CTYPEia. Wildcarding may be used as for the ctypeS2 argument to spctrn() as described in the prologue of spc.h, i.e. if the final three characters are
		specified as "???", or if just the eighth character is specified as '?', the correct algorithm
		code will be substituted and returned.

Returns

Status return value:

- 0: Success.
- 1: Null wcsprm pointer passed.
- 2: Memory allocation failed.
- 3: Linear transformation matrix is singular.
- 4: Inconsistent or unrecognized coordinate axis types.
- 5: Invalid parameter value.
- 6: Invalid coordinate transformation parameters.
- 7: Ill-conditioned coordinate transformation parameters.
- 12: Invalid subimage specification (no spectral axis).

For returns > 1, a detailed error message is set in wcsprm::err if enabled, see wcserr_enable().

00061 *
00062 * These routines are based on the wcsprm struct which contains all information
00063 \star needed for the computations. The struct contains some members that must be
00064 \star set by the user, and others that are maintained by these routines, somewhat
00065 * like a C++ class but with no encapsulation.
00066 *
00067 * wcsnpv(), wcsnps(), wcsini(), wcsinit(), wcssub(), wcsfree(), and wcstrim(),
00068 \star are provided to manage the wcsprm struct, wcssize() computes its total size
00069 \star including allocated memory, wcsenq() returns information about the state of
00070 * the struct, and wcsprt() prints its contents. wcscopy(), which does a deep
00071 \star copy of one wcsprm struct to another, is defined as a preprocessor macro
00072 \star function that invokes wcssub().
00073 *
00074 \star wcsperr() prints the error message(s) (if any) stored in a wcsprm struct,
00075 \star and the linprm, celprm, prjprm, spcprm, and tabprm structs that it contains.
00077 \star A setup routine, wcsset(), computes intermediate values in the wcsprm struct
00078 \star from parameters in it that were supplied by the user. The struct always
00079 \star needs to be set up by wcsset() but this need not be called explicitly
00080 * refer to the explanation of wcsprm::flag.
00081 *
00082 * wcsp2s() and wcss2p() implement the WCS world coordinate transformations.
00083 * In fact, they are high level driver routines for the WCS linear,
```

```
00084 \star logarithmic, celestial, spectral and tabular transformation routines
00085 * described in lin.h, log.h, cel.h, spc.h and tab.h.
00086 *
00087 \star Given either the celestial longitude or latitude plus an element of the
00088 \star pixel coordinate a hybrid routine, wcsmix(), iteratively solves for the
00089 * unknown elements.
00091 \star wcsccs() changes the celestial coordinate system of a wcsprm struct, for
00092 \star example, from equatorial to galactic, and wcssptr() translates the spectral 00093 \star axis. For example, a 'FREQ' axis may be translated into 'ZOPT-F2W' and vice
00094 * versa.
00095 *
00096 * wcslib_version() returns the WCSLIB version number.
00097 *

00123 *
          routines.
00124 *
00125 *
00126 * wcsnpv() - Memory allocation for PVi ma
00127 *
00128 \star wcsnpv() sets or gets the value of NPVMAX (default 64). This global
00129 \star variable controls the number of pvcard structs, for holding PVi_ma
00130 \star keyvalues, that wcsini() should allocate space for. It is also used by
00131 * wcsinit() as the default value of npvmax.
00132 *
00133 * PLEASE NOTE: This function is not thread-safe.
00134 *
00135 * Given:
00136 *
                     int
                                Value of NPVMAX; ignored if < 0. Use a value less
00137 *
                               than zero to get the current value.
00138 *
00139 * Function return value:
                                Current value of NPVMAX.
                    int
00141 *
00142 *
00143 * wcsnps() - Memory allocation for PSi_ma
00144 * ----
00145 \star wcsnps() sets or gets the value of NPSMAX (default 8). This global variable
00146 * wosings() sets of gets the variety of motion (action of the controls the number of pscard structs, for holding PSi_ma keyvalues, that 00147 * wosini() should allocate space for. It is also used by wosinit() as the
00148 * default value of npsmax.
00149 *
00150 * PLEASE NOTE: This function is not thread-safe.
00151 *
00152 * Given:
00153 * n
                     int
                                Value of NPSMAX; ignored if < 0. Use a value less
00154 *
                               than zero to get the current value.
00155 *
00156 * Function return value:
                                Current value of NPSMAX.
00157 *
                    int
00158 *
00159 *
00160 * wcsini() - Default constructor for the wcsprm struct
00161 *
00162 \star wcsini() is a thin wrapper on wcsinit(). It invokes it with npvmax,
00163 \star npsmax, and ndpmax set to -1 which causes it to use the values of the
00164 * global variables NDPMAX, NPSMAX, and NDPMAX. It is thereby potentially
00165 * thread-unsafe if these variables are altered dynamically via wcsnpv(),
00166 \star wcsnps(), and disndp(). Use wcsinit() for a thread-safe alternative in
00167 * this case.
00168 *
00169
00170 * wcsinit() - Default constructor for the wcsprm struct
```

```
00172 \star wcsinit() optionally allocates memory for arrays in a wcsprm struct and sets
00173 * all members of the struct to default values.
00174 *
00175 * PLEASE NOTE: every wcsprm struct should be initialized by wcsinit(),
00176 \star possibly repeatedly. On the first invokation, and only the first 00177 \star invokation, wcsprm::flag must be set to -1 to initialize memory management,
00178 \star regardless of whether wcsinit() will actually be used to allocate memory.
00179 *
00180 * Given:
                                 If true, allocate memory unconditionally for the
00181 *
          alloc
                     int
00182 *
                                 crpix, etc. arrays. Please note that memory is never
00183 *
                                 allocated by wcsinit() for the auxprm, tabprm, nor
00184 *
                                 wtbarr structs.
00185 *
00186 *
                                 If false, it is assumed that pointers to these arrays
00187 *
                                 have been set by the user except if they are null
                                 pointers in which case memory will be allocated for
00188 *
00189
                                 them regardless. (In other words, setting alloc true
00190 *
                                 saves having to initalize these pointers to zero.)
00191 *
00192 *
           naxis
                                 The number of world coordinate axes. This is used to
00193 *
                                 determine the length of the various wcsprm vectors and
00194 *
                                 matrices and therefore the amount of memory to
00195 *
                                 allocate for them.
00196 *
00197 * Given and returned:
00198 *
                     struct wcsprm*
00199 *
                                 Coordinate transformation parameters.
00200 *
00201 *
                                 Note that, in order to initialize memory management,
00202 *
                                 wcsprm::flag should be set to -1 when wcs is
00203 *
                                 initialized for the first time (memory leaks may
00204 *
                                 result if it had already been initialized).
00205 *
00206 * Given:
00207 *
                                 The number of PVi_ma keywords to allocate space for.
          npvmax
                      int
                                 If set to -1, the value of the global variable NPVMAX will be used. This is potentially thread-unsafe if
00208 *
00209 *
00210 *
                                 wcsnpv() is being used dynamically to alter its value.
00211 *
00212 *
          npsmax
                      int
                                 The number of PSi_ma keywords to allocate space for.
                                 If set to -1, the value of the global variable NPSMAX will be used. This is potentially thread-unsafe if
00213 *
00214 *
00215 *
                                 wcsnps() is being used dynamically to alter its value.
00216 *
00217 *
                                 The number of DPja or DQia keywords to allocate space
          ndpmax
                      int
                                 for. If set to -1, the value of the global variable NDPMAX will be used. This is potentially thread-unsafe if disndp() is being used dynamically to
00218 *
00219 *
00220 *
00221 *
                                 alter its value.
00222 *
00223 * Function return value:
00224 *
                                 Status return value:
                     int
00225 *
                                   0: Success.
00226 *
                                   1: Null wcsprm pointer passed.
                                   2: Memory allocation failed.
00228 *
00229 *
                                 For returns > 1, a detailed error message is set in
00230 *
                                 wcsprm::err if enabled, see wcserr_enable().
00231 *
00232 *
00233 * wcsauxi() - Default constructor for the auxprm struct
00234 *
00235 \star wcsauxi() optionally allocates memory for an auxprm struct, attaches it to
00236 \star wcsprm, and sets all members of the struct to default values.
00237 *
00238 * Given:
00239 *
                     int
                                If true, allocate memory unconditionally for the
          alloc
                                 auxprm struct.
00240 *
00241 *
00242 *
                                 If false, it is assumed that wcsprm::aux has already
00243 *
                                 been set to point to an auxprm struct, in which case
00244 *
                                 the user is responsible for managing that memory.
00245 *
                                 However, if wcsprm::aux is a null pointer, memory will
00246
                                 be allocated regardless. (In other words, setting
00247 *
                                 alloc true saves having to initalize the pointer to
00248 *
00249 *
00250 * Given and returned:
00251 *
          WCS
                    struct wcsprm*
                                 Coordinate transformation parameters.
00253 *
00254 * Function return value:
00255 *
                     int
                                 Status return value:
                                   0: Success.
00256 *
00257 *
                                   1: Null wcsprm pointer passed.
```

```
2: Memory allocation failed.
00259 *
00260 *
00261 * wcssub() - Subimage extraction routine for the wcsprm struct
00262 * ---
00263 \star wcssub() extracts the coordinate description for a subimage from a wcsprm
00264 * struct. It does a deep copy, using wcsinit() to allocate memory for its 00265 * arrays if required. Only the "information to be provided" part of the
00266 \star struct is extracted. Consequently, wcsset() need not have been, and won't
00267 \star be invoked on the struct from which the subimage is extracted. A call to
00268 * wcsset() is required to set up the subimage struct.
00269 *
00270 \star The world coordinate system of the subimage must be separable in the sense
00271 * that the world coordinates at any point in the subimage must depend only on
00272 \star the pixel coordinates of the axes extracted. In practice, this means that
00273 \star the linear transformation matrix of the original image must not contain
00274 \star non-zero off-diagonal terms that associate any of the subimage axes with any
00275 \star of the non-subimage axes. Likewise, if any distortions are associated with
00276 \star the subimage axes, they must not depend on any of the axes that are not
00277 * being extracted.
00278 *
00279 \star Note that while the required elements of the tabprm array are extracted, the
00280 \star wtbarr array is not. (Thus it is not appropriate to call wcssub() after
00281 \star wcstab() but before filling the tabprm structs - refer to wcshdr.h.)
00282 *
00283 * wcssub() can also add axes to a wcsprm struct. The new axes will be created
00284 \star using the defaults set by wcsinit() which produce a simple, unnamed, linear
00285 \star axis with world coordinate equal to the pixel coordinate. These default
00286 \star values can be changed afterwards, before invoking wcsset().
00287 *
00288 * Given:
00289 *
         alloc
                               If true, allocate memory for the crpix, etc. arrays in
                    int
00290 *
                               the destination. Otherwise, it is assumed that
00291 *
                               pointers to these arrays have been set by the user
00292 *
                                except if they are null pointers in which case memory
00293 *
                               will be allocated for them regardless.
00294 *
00295 *
          wcssrc
                   const struct wcsprm*
00296 *
                               Struct to extract from.

                               subimage, etc.
00305 *
00306 *
                               Use an axis number of 0 to create a new axis using
00307 *
                               the defaults set by wcsinit(). They can be changed
00308 *
                                later.
00309 *
00310 *
                                nsub (the pointer) may be set to zero, and so also may
00311 *
                                \starnsub, which is interpreted to mean all axes in the
00312 *
                                input image; the number of axes will be returned if
00313 *
                                nsub != 0x0. axes itself (the pointer) may be set to
                                zero to indicate the first *nsub axes in their
00314 *
00315 *
                               original order.
00316 *
00317 *
                               Set both nsub (or *nsub) and axes to zero to do a deep
00318 *
                               copy of one wcsprm struct to another.
00319 *
00320 *
                                Subimage extraction by coordinate axis type may be
                               done by setting the elements of axes[] to the
00321 *
00322 *
                                following special preprocessor macro values:
00323 *
00324 *
                                 WCSSUB_LONGITUDE: Celestial longitude.
00325 *
                                 WCSSUB_LATITUDE: Celestial latitude.
WCSSUB_CUBEFACE: Quadcube CUBEFACE axis.
00326 *
00327 *
                                 WCSSUB_SPECTRAL:
                                                    Spectral axis.
00328 *
                                 WCSSUB_STOKES:
                                                    Stokes axis.
00329 +
                                 WCSSUB TIME:
                                                    Time axis.
00330 *
00331 *
                               Refer to the notes (below) for further usage examples.
00332 *
00333
                                On return, *nsub will be set to the number of axes in
00334 *
                                the subimage; this may be zero if there were no axes
00335 *
                                of the required type(s) (in which case no memory will
00336 *
                                be allocated). axes[] will contain the axis numbers
00337 *
                                that were extracted, or 0 for newly created axes. The
                                vector length must be sufficient to contain all axis
00338 *
00339 *
                               numbers. No checks are performed to verify that the
00340 *
                               coordinate axes are consistent, this is done by
00341 *
                               wcsset().
00342 *
00343 *

                    struct wcsprm*
00344 *
                               Struct describing the subimage. wcsprm::flag should
```

```
be set to -1 if wcsdst was not previously initialized
00346 *
                                (memory leaks may result if it was previously
00347 *
                               initialized).
00348 *
00349 * Function return value:
00350 *
                               Status return value:
                    int
                                  0: Success.
00352 *
                                  1: Null wcsprm pointer passed.
00353 *
                                  2: Memory allocation failed.
00354 *
                                12: Invalid subimage specification.
00355 *
                                13: Non-separable subimage coordinate system.
00356 *
00357 *
                               For returns > 1, a detailed error message is set in
                               wcsprm::err if enabled, see wcserr_enable().
00358 *
00359 *
00360 * Notes:
00361 *
          1: Combinations of subimage axes of particular types may be extracted in
             the same order as they occur in the input image by combining preprocessor codes, for example
00362 *
00363 *
00364 *
00365 =
               *nsub = 1;
00366 =
               axes[0] = WCSSUB_LONGITUDE | WCSSUB_LATITUDE | WCSSUB_SPECTRAL;
00367 *
             would extract the longitude, latitude, and spectral axes in the same order as the input image. If one of each were present, \starnsub = 3 would
00368 *
00369 *
00370 *
             be returned.
00371 *
00372 *
             For convenience, \mbox{WCSSUB\_CELESTIAL} is defined as the combination
00373 *
             WCSSUB_LONGITUDE | WCSSUB_LATITUDE | WCSSUB_CUBEFACE.
00374 *
00375 *
             The codes may also be negated to extract all but the types specified,
00376 *
             for example
00377 *
00378 =
               *nsub = 4;
               axes[0] = WCSSUB_LONGITUDE;
axes[1] = WCSSUB_LATITUDE;
00379 =
00380 =
               axes[2] = WCSSUB_CUBEFACE;
00381 =
00382 =
               axes[3] = -(WCSSUB_SPECTRAL | WCSSUB_STOKES);
00383 *
00384 *
             The last of these specifies all axis types other than spectral or
00385 *
             Stokes. Extraction is done in the order specified by axes[] a
             longitude axis (if present) would be extracted first (via axes[0]) and
00386 *
00387 *
             not subsequently (via axes[3]). Likewise for the latitude and cubeface
00388 *
             axes in this example.
00389 *
00390 *
             From the foregoing, it is apparent that the value of *nsub returned may
00391 *
             be less than or greater than that given. However, it will never exceed
00392 *
             the number of axes in the input image (plus the number of newly-created
00393 *
             axes if any were specified on input).
00394 *
00395 *
00396 * wcscompare() - Compare two wcsprm structs for equality
00397 *
00398 \star wcscompare() compares two wcsprm structs for equality.
00399 *
00400 * Given:
00401 *
                               A bit field controlling the strictness of the
         cmp
00402 *
                               comparison. When 0, all fields must be identical.
00403 *
00404 *
                               The following constants may be or'ed together to
00405 *
                               relax the comparison:
00406 *
                                  WCSCOMPARE_ANCILLARY: Ignore ancillary keywords
00407 *
                                    that don't change the WCS transformation, such
00408 *
                                    as DATE-OBS or EQUINOX.
00409
                                  WCSCOMPARE_TILING: Ignore integral differences in
00410 *
                                    CRPIXja. This is the 'tiling' condition, where
00411 *
                                    two WCSes cover different regions of the same \,
00412 *
                                    map projection and align on the same map grid.
                                  WCSCOMPARE_CRPIX: Ignore any differences at all in
00413 *
00414 *
                                    CRPIXja. The two WCSes cover different regions
00415 *
                                    of the same map projection but may not align on
00416 *
                                    the same map grid. Overrides WCSCOMPARE_TILING.
00417 *
00418 *
          tol
                               Tolerance for comparison of floating-point values.
                     double
                               For example, for tol == 1e-6, all floating-point
00419 *
00420 *
                               values in the structs must be equal to the first 6
00421 *
                               decimal places. A value of 0 implies exact equality.
00422 *
00423 *
          wcs1
                     const struct wcsprm*
00424 *
                               The first wcsprm struct to compare.
00425 *
00426 *
          wcs2
                     const struct wcsprm*
00427 *
                               The second wcsprm struct to compare.
00428 *
00429 * Returned:
00430 *
          equal
                     int.*
                               Non-zero when the given structs are equal.
00431 *
```

```
00432 * Function return value:
                                Status return value:
00433 *
                    int
00434 *
                                   0: Success.
00435 *
                                   1: Null pointer passed.
00436 *
00437 *
00438 * wcscopy() macro - Copy routine for the wcsprm struct
00439 *
00440 \, \star \, \text{wcscopy}() does a deep copy of one wcsprm struct to another. As of
00441 \star WCSLIB 3.6, it is implemented as a preprocessor macro that invokes
00442 * wcssub() with the nsub and axes pointers both set to zero.
00443 *
00444 *
00445 * wcsfree() - Destructor for the wcsprm struct
00446 *
00447 \star wcsfree() frees memory allocated for the wcsprm arrays by wcsinit() and/or 00448 \star wcsset(). wcsinit() records the memory it allocates and wcsfree() will only
00449 * attempt to free this.
00450 *
00451 * PLEASE NOTE: wcsfree() must not be invoked on a wcsprm struct that was not
00452 * initialized by wcsinit().
00453 *
00454 * Given and returned:
00455 * wcs
                     struct wcsprm*
00456 *
                                Coordinate transformation parameters.
00457 *
00458 * Function return value:
00459 *
                     int
                                Status return value:
00460 *
                                   0: Success.
00461 *
                                   1: Null wcsprm pointer passed.
00462 *
00463 *
00464 * wcstrim() - Free unused arrays in the wcsprm struct
00465 *
00466 \star wcstrim() frees memory allocated by wcsinit() for arrays in the wcsprm 00467 \star struct that remains unused after it has been set up by wcsset().
00468 *
00469 \star The free'd array members are associated with FITS WCS keyrecords that are
00470 * rarely used and usually just bloat the struct: wcsprm::crota, wcsprm::colax,
00471 * wcsprm::cname, wcsprm::crder, wcsprm::csyer, wcsprm::czphs, and
00472 * wcsprm::cperi. If unused, wcsprm::pv, wcsprm::ps, and wcsprm::cd are also
00473 * freed.
00474 *
00475 \star Once these arrays have been freed, a test such as
00476 =
00477 =
                if (!undefined(wcs->cname[i])) {...}
00478 =
00479 \star must be protected as follows
00480 =
                if (wcs->cname && !undefined(wcs->cname[i])) {...}
00481 =
00482 =
00483 * In addition, if wcsprm::npv is non-zero but less than wcsprm::npvmax, then
00484 \star the unused space in wcsprm::pv will be recovered (using realloc()).
00485 * Likewise for wcsprm::ps.
00486 *
00487 * Given and returned:
00488 * wcs
                    struct wcsprm*
00489 *
                                 Coordinate transformation parameters.
00490 *
00491 * Function return value:
00492 *
                     int
                                Status return value:
00493 *
                                  0: Success.
00494 *
                                   1: Null wcsprm pointer passed.
00495 *
                                  14: wcsprm struct is unset.
00496 *
00497 *
00498 * wcssize() - Compute the size of a wcsprm struct
00499 * ---
00500 * wcssize() computes the full size of a wcsprm struct, including allocated
00501 * memory.
00502 *
00503 * Given:
00504 * wcs
                   const struct wcsprm*
00505 *
                                Coordinate transformation parameters.
00506 *
00507 *
                                 If NULL, the base size of the struct and the allocated
00508 *
                                size are both set to zero.
00509 *
00510 * Returned:
00511 *
                     int[2]
                                The first element is the base size of the struct as
          sizes
                                returned by sizeof(struct wcsprm). The second element
00512 *
                                 is the total allocated size, in bytes, assuming that
                                the allocation was done by wcsini(). This figure includes memory allocated for members of constituent
00514 *
00515 *
00516 *
                                 structs, such as wcsprm::lin.
00517 *
00518 *
                                 It is not an error for the struct not to have been set
```

```
00519 *
                               up via wcsset(), which normally results in additional
00520 *
                              memory allocation.
00521 *
00522 * Function return value:
00523 *
                   int
                              Status return value:
00524 *
                                0: Success.
00525 *
00526 *
00527 * auxsize() - Compute the size of a auxprm struct
00528 *
00529 * auxsize() computes the full size of an auxprm struct, including allocated
00530 * memory.
00531 *
00532 * Given:
00533 *
                    const struct auxprm*
00534 *
                              Auxiliary coordinate information.
00535 *
00536 *
                              If NULL, the base size of the struct and the allocated
                              size are both set to zero.
00537 *
00538 *
00539 * Returned:
00540 *
         sizes
                    int[2]
                            The first element is the base size of the struct as
00541 *
                              returned by sizeof(struct auxprm). The second element
00542 *
                              is the total allocated size, in bytes, currently zero.
00543 *
00544 * Function return value:
00545 *
                            Status return value:
00546 *
                                0: Success.
00547 *
00548 *
00549 * wcseng() - enquire about the state of a wcsprm struct
00550 *
00551 * wcsenq() may be used to obtain information about the state of a wcsprm
00552 \star struct. The function returns a true/false answer for the enquiry asked.
00553 *
00554 * Given:
00555 *
         WCS
                   const struct wcsprm*
00556 *
                              Coordinate transformation parameters.
00557 *
00558 *
                              Enquiry according to the following parameters:
         enquiry int
00559 *
                                 WCSENQ_MEM: memory in the struct is being managed by
                                             WCSLIB (see wcsini()).
00560 *
                                 WCSENQ_SET: the struct has been set up by wcsset().
00561 *
00562 *
                                WCSENO_BYP: the struct is in bypass mode (see
00563 *
                                             wcsset()).
00564 *
                                 WCSENQ_CHK: the struct is self-consistent in that
00565 *
                                             no changes have been made to any of the
00566 *
                                             "parameters to be given" since the last
00567 *
                                             call to wcsset().
                               These may be combined by logical OR, e.g. WCSENQ_MEM | WCSENQ_SET. The enquiry result will be
00568 *
00569
00570 *
                               the logical AND of the individual results.
00571 *
00572 * Function return value:
00573 *
                              Enquiry result:
                    int
00574 *
                                0: False.
00575 *
                                 1: True.
00576 *
00577 *
00578 * wcsprt() - Print routine for the wcsprm struct
00579 *
00580 * wcsprt() prints the contents of a wcsprm struct using wcsprintf(). Mainly
00581 * intended for diagnostic purposes.
00582 *
00583 * Given:
00584 * wcs
                   const struct wcsprm*
00585 *
                              Coordinate transformation parameters.
00586 *
00587 * Function return value:
                   int
                            Status return value:
00589 *
                                 0: Success.
00590 +
                                 1: Null wcsprm pointer passed.
00591 *
00592 *
00593 * wcsperr() - Print error messages from a wcsprm struct
00594 *
00595 \star wcsperr() prints the error message(s), if any, stored in a wcsprm struct,
00596 \star and the linprm, celprm, prjprm, spcprm, and tabprm structs that it contains.
00597 * If there are no errors then nothing is printed. It uses wcserr_prt(), q.v.
00598 *
00599 * Given:
00600 *
                   const struct wcsprm*
         WCS
                              Coordinate transformation parameters.
00601 *
00602 *
         prefix
00603 *
                    const char *
                               If non-NULL, each output line will be prefixed with
00604 *
00605 *
                              this string.
```

```
00607 * Function return value:
                    int
00608 *
                                 Status return value:
00609 *
                                   0: Success.
00610 *
                                   1: Null wcsprm pointer passed.
00611 *
00612 *
00613 * wcsbchk() - Enable/disable bounds checking
00614 *
00615 \star wcsbchk() is used to control bounds checking in the projection routines.
00616 * Note that wcsset() always enables bounds checking. wcsbchk() will invoke
00617 \star wcsset() on the wcsprm struct beforehand if necessary.
00618 *
00619 * Given and returned:
00620 *
          wcs struct wcsprm*
00621 *
                                 Coordinate transformation parameters.
00622 *
00623 * Given:
00624 *
          bounds
                                If bounds&1 then enable strict bounds checking for the
00625 *
                                 spherical-to-Cartesian (s2x) transformation for the
00626 *
                                 AZP, SZP, TAN, SIN, ZPN, and COP projections.
00627 *
00628 *
                                 If bounds&2 then enable strict bounds checking for the
00629 *
                                 Cartesian-to-spherical (x2s) transformation for the
00630 *
                                 HPX and XPH projections.
00632
                                 If bounds&4 then enable bounds checking on the native
00633 *
                                 coordinates returned by the Cartesian-to-spherical
00634 *
                                 (x2s) transformations using prjchk().
00635 *
00636 *
                                 Zero it to disable all checking.
00637 *
00638 * Function return value:
00639 *
                                 Status return value:
                     int
00640 *
                                   0: Success.
00641 *
                                   1: Null wcsprm pointer passed.
00642 *
00643 *
00644 * wcsset() - Setup routine for the wcsprm struct
00645 *
00646 \star wcsset() sets up a wcsprm struct according to information supplied within
00647 \star it (refer to the description of the wcsprm struct).
00648 *
00649 \star wcsset() recognizes the NCP projection and converts it to the equivalent SIN
00650 \star projection and likewise translates GLS into SFL. It also translates the
00651 \star AIPS spectral types ('FREQ-LSR', 'FELO-HEL', etc.), possibly changing the
00652 * input header keywords wcsprm::ctype and/or wcsprm::specsys if necessary.
00653 *
00654 * Note that this routine need not be called directly; it will be invoked by
00655 * wcsp2s() and wcss2p() if the wcsprm::flag is anything other than a
00656 * predefined magic value.
00657 *
00658 \star wcsset() normally operates regardless of the value of wcsprm::flag; i.e.
00659 * even if a struct was previously set up it will be reset unconditionally.

00660 * However, a wesprm struct may be put into "bypass" mode by invoking wesset()

00661 * initially with wesprm::flag == 1 (rather than 0). wesset() will return

00662 * immediately if invoked on a struct in that state. To take a struct out of
00663 * bypass mode, simply reset wcsprm::flag to zero. See also wcsenq().
00664 *
00665 * Given and returned:
                   struct wcsprm*
00666 * wcs
00667 *
                                 Coordinate transformation parameters.
00668 *
00669 * Function return value:
00670 *
                                 Status return value:
                      int
00671 *
                                   0: Success.
00672 *
                                   1: Null wcsprm pointer passed.
00673 *
                                   2: Memory allocation failed.3: Linear transformation matrix is singular.
00674 *
                                   4: Inconsistent or unrecognized coordinate axis
00676 *
                                       types.
00677 *
                                   5: Invalid parameter value.
00678 *
                                   6: Invalid coordinate transformation parameters.
00679 *
                                   7: Ill-conditioned coordinate transformation
00680 *
                                       parameters.
00681 *
00682 *
                                 For returns > 1, a detailed error message is set in
00683 *
                                 wcsprm::err if enabled, see wcserr_enable().
00684 *
00685 * Notes:
00686 \star 1: wcsset() always enables strict bounds checking in the projection
              routines (via a call to prjini()). Use wcsbchk() to modify
              bounds-checking after wcsset() is invoked.
00688 *
00689 *
00690 *
00691 * wcsp2s() - Pixel-to-world transformation
00692 * --
```

```
00693 * wcsp2s() transforms pixel coordinates to world coordinates.
00695 * Given and returned:
00696 *
         WCS
                   struct wcsprm*
00697 *
                               Coordinate transformation parameters.
00698 *
00699 * Given:
00700 *
         ncoord,
00701 *
                               The number of coordinates, each of vector length
          nelem
                    int
00702 *
                               nelem but containing wcs.naxis coordinate elements.
00703 *
                               Thus nelem must equal or exceed the value of the
00704 *
                               NAXIS keyword unless noord == 1, in which case nelem
00705 *
                               is not used.
00706 *
00707 *
         pixcrd
                    const double[ncoord][nelem]
00708 *
                              Array of pixel coordinates.
00709 *
00710 * Returned:
00711 *
                    double[ncoord][nelem]
         imgcrd
00712 *
                               Array of intermediate world coordinates. For
00713 *
                               celestial axes, imgcrd[][wcs.lng] and
00714 *
                               imgcrd[][wcs.lat] are the projected x-, and
                               y-coordinates in pseudo "degrees". For spectral
00715 *
00716 *
                               axes, imgcrd[][wcs.spec] is the intermediate spectral
00717 *
                               coordinate, in SI units. For time axes,
00718
                               imgcrd[][wcs.time] is the intermediate time
00719
                               coordinate.
00720 *
00721 *
          phi,theta double[ncoord]
                               Longitude and latitude in the native coordinate system
00722 *
00723 *
                               of the projection [deg].
00724 *
00725 *
          world
                    double[ncoord][nelem]

00902 *
                                                                         7: Ill-conditioned coordinate transformation
00903 *
                                                                               parameters.
                                                                       10: Invalid world coordinate.
00905 *
                                                                       11: No solution found in the specified interval.
00906 *
00907 *
                                                                    For returns > 1, a detailed error message is set in
                                                                    wcsprm::err if enabled, see wcserr_enable().
00908 *
00909 *
00910 * Notes:
                 1: Initially the specified solution interval is checked to see if it's a "crossing" interval. If it isn't, a search is made for a crossing
00912 *
00913 *
                              solution by iterating on the unknown celestial coordinate starting at
00914 *
                             the upper limit of the solution interval and decrementing by the % \left( 1\right) =\left( 1\right) +\left( 1\right) +\left
00915 *
                             specified step size. A crossing is indicated if the trial value of the pixel coordinate steps through the value specified. If a crossing
00916 *
                              interval is found then the solution is determined by a modified form of
00918 *
                             "regula falsi" division of the crossing interval. If no crossing
00919 *
                             interval was found within the specified solution interval then a search
                             is made for a "non-crossing" solution as may arise from a point of tangency. The process is complicated by having to make allowance for \frac{1}{2}
00920 *
00921 *
00922 *
                             the discontinuities that occur in all map projections.
00924 *
                             Once one solution has been determined others may be found by subsequent
00925 *
                             invokations of wcsmix() with suitably restricted solution intervals.
00926 *
00927 *
                             Note the circumstance that arises when the solution point lies at a
00928 *
                             native pole of a projection in which the pole is represented as a
00929 *
                             finite curve, for example the zenithals and conics. In such cases two
                             or more valid solutions may exist but wcsmix() only ever returns one.
00930 *
00931 *
00932 *
                             Because of its generality wcsmix() is very compute-intensive. For
                             compute-limited applications more efficient special-case solvers could
00933 *
00934 *
                             be written for simple projections, for example non-oblique cylindrical
00935 *
                             projections.
00937
00938 * wcsccs() - Change celestial coordinate system
00939 * ---
00940 * wcsccs() changes the celestial coordinate system of a wcsprm struct. For
00941 * example, from equatorial to galactic coordinates.
00942 *
00943 * Parameters that define the spherical coordinate transformation, essentially
00944 * being three Euler angles, must be provided. Thereby wcsccs() does not need
00945 \star prior knowledge of specific celestial coordinate systems. It also has the
00946 \star advantage of making it completely general.
00947 *
00948 \star Auxiliary members of the wcsprm struct relating to equatorial celestial
00949 * coordinate systems may also be changed.
00950 *
00951 \star Only orthodox spherical coordinate systems are supported. That is, they
00952 \star must be right-handed, with latitude increasing from zero at the equator to 00953 \star +90 degrees at the pole. This precludes systems such as aziumuth and zenith
```

```
00954 \star distance, which, however, could be handled as negative azimuth and
00956 *
00957 \star PLEASE NOTE: Information in the wcsprm struct relating to the original
00958 \star coordinate system will be overwritten and therefore lost. If this is 00959 \star undesirable, invoke wcsccs() on a copy of the struct made with wcssub().
00960 * The wcsprm struct is reset on return with an explicit call to wcsset().
00961 *
00962 * Given and returned:
00963 *
          WCS
                      struct wcsprm*
00964 *
                                  Coordinate transformation parameters. Particular
                                   "values to be given" elements of the wcsprm struct
00965 *
00966 *
                                  are modified.
00967 *
00968 * Given:
00969 *
           lng2p1,
00970 *
                                  Longitude and latitude in the new celestial coordinate system of the pole (i.e. latitude +90) of the original system [deg]. See notes 1 and 2 below.
           lat2p1
                      double
00971 *
00973 *
00974 *
           lng1p2
                      double
                                  Longitude in the original celestial coordinate system
                                  of the pole (i.e. latitude +90) of the new system [deg]. See note 1 below.
00975 *
00976 *
00977 *
00978 *
           clng, clat const char*
00979 *
                                  Longitude and latitude identifiers of the new CTYPEia
                                  celestial axis codes, without trailing dashes. For example, "RA" and "DEC" or "GLON" and "GLAT". Up to
00980 *
00981 *
00982 *
                                  four characters are used, longer strings need not be
00983 *
                                  null-terminated.
00984 *
00985 *
           radesvs
                      const char*
00986 *
                                  Used when transforming to equatorial coordinates, identified by clng == "RA" and clat = "DEC". May be
00987 *
                                  set to the null pointer to preserve the current value.
00988 *
00989 *
                                  Up to 71 characters are used, longer strings need not
00990 *
                                  be null-terminated.
00991 *
00992 *
                                  If the new coordinate system is anything other than
00993 *
                                  equatorial, then wcsprm::radesys will be cleared.
00994 *
00995 *
           equinox double
                                  Used when transforming to equatorial coordinates. May
00996 *
                                  be set to zero to preserve the current value.
00997 *
00998 *
                                  If the new coordinate system is not equatorial, then
00999 *
                                  wcsprm::equinox will be marked as undefined.
01000 *
01001 *
           alt
                      const char*
01002 *
                                  Character code for alternate coordinate descriptions
01003 *
                                  (i.e. the 'a' in keyword names such as CTYPEia). This
01004 *
                                  is blank for the primary coordinate description, or
01005 *
                                  one of the 26 upper-case letters, A-Z. May be set to
01006 *
                                  the null pointer, or null string if no change is
01007 *
                                  required.
01008 *
01009 * Function return value:
                                  Status return value:
                      int
01011 *
                                    0: Success.
01012 *
                                     1: Null wcsprm pointer passed.
01013 *
                                   12: Invalid subimage specification (no celestial
01014 *
                                        axes).
01015 *
01016 * Notes:
01017 *
          1: Follows the prescription given in WCS Paper II, Sect. 2.7 for changing
01018 *
               celestial coordinates.
01019 *
               The implementation takes account of indeterminacies that arise in that
01020 *
01021 *
               prescription in the particular cases where one of the poles of the new
               system is at the fiducial point, or one of them is at the native pole.
01022 *
01023 *
01024 *
           2: If lat2p1 == +90, i.e. where the poles of the two coordinate systems
01025 *
               coincide, then the spherical coordinate transformation becomes a simple
               change in origin of longitude given by lng2 = lng1 + (lng2p1 - lng1p2 - 180), and lat2 = lat1, where
01026 *
01027 *
              (lng2,lat2) are coordinates in the new system, and (lng1,lat1) are coordinates in the original system.
01028 *
01029 *
01030 *
01031 *
               Likewise, if lat2p1 == -90, then lng2 = -lng1 + (lng2p1 + lng1p2), and
01032 *
               lat2 = -lat1.
01033 *
01034 *
           3: For example, if the original coordinate system is B1950 equatorial and
01035 *
               the desired new coordinate system is galactic, then
01036 *
01037 *
               - (lng2p1,lat2p1) are the galactic coordinates of the B1950 celestial
01038 *
                 pole, defined by the IAU to be (123.0,+27.4), and lng1p2 is the B1950
                 right ascension of the galactic pole, defined as 192.25. Clearly these coordinates are fixed for a particular coordinate
01039 *
01040 *
```

```
transformation.
01042 *
              - (clng,clat) would be 'GLON' and 'GLAT', these being the FITS standard
01043 *
01044 *
               identifiers for galactic coordinates.
01045 *
01046 *
              - Since the new coordinate system is not equatorial, wcsprm::radesys
               and wcsprm::equinox will be cleared.
01048 *
01049 *
          4. The coordinates required for some common transformations (obtained from
01050 *
              https://ned.ipac.caltech.edu/coordinate_calculator) are as follows:
01051 *
01052 =
              (123.0000,+27.4000) galactic coordinates of B1950 celestial pole,
01053 =
              (192.2500, +27.4000) B1950 equatorial coordinates of galactic pole.
01054 *
01055 =
              (122.9319,+27.1283) galactic coordinates of J2000 celestial pole,
01056 =
              (192.8595,+27.1283) J2000 equatorial coordinates of galactic pole.
01057 *
01058 =
              (359.6774,+89.7217) B1950 equatorial coordinates of J2000 pole,
              (180.3162, +89.7217) J2000 equatorial coordinates of B1950 pole.
01059 =
01060 *
              (270.0000,+66.5542) B1950 equatorial coordinates of B1950 ecliptic pole,
01061 =
01062 =
              ( 90.0000,+66.5542) B1950 ecliptic coordinates of B1950 celestial pole.
01063 *
              (270.0000,+66.5607) J2000 equatorial coordinates of J2000 ecliptic pole,
01064 =
01065 =
              (90.0000,+66.5607) J2000 ecliptic coordinates of J2000 celestial pole.
01066 *
01067 =
              ( 26.7315,+15.6441) supergalactic coordinates of B1950 celestial pole,
01068 =
              (283.1894,+15.6441) B1950 equatorial coordinates of supergalactic pole.
01069 *
              ( 26.4505,+15.7089) supergalactic coordinates of J2000 celestial pole,
01070 =
01071 =
              (283.7542,+15.7089) J2000 equatorial coordinates of supergalactic pole.
01072 *
01073 *
01074 * wcssptr() - Spectral axis translation
01075 *
01076 \star wcssptr() translates the spectral axis in a wcsprm struct. For example, a
01077 \star 'FREQ' axis may be translated into 'ZOPT-F2W' and vice versa.
01079 \star PLEASE NOTE: Information in the wcsprm struct relating to the original
01080 \star coordinate system will be overwritten and therefore lost. If this is
01081 \star undesirable, invoke wcssptr() on a copy of the struct made with wcssub().
01082 * The wcsprm struct is reset on return with an explicit call to wcsset().
01083 *
01084 * Given and returned:
01085 *

01100 *
                     int
                                Status return value:
01101 *
                                  0: Success.
01102 *
                                  1: Null wcsprm pointer passed.
01103 *
                                  2: Memory allocation failed.
                                   3: Linear transformation matrix is singular.
01104 *
01105 *
                                  4: Inconsistent or unrecognized coordinate axis
01106 *
                                     types.
01107 *
                                  5: Invalid parameter value.
01108 *
                                  6: Invalid coordinate transformation parameters.
01109 *
                                  7: Ill-conditioned coordinate transformation
01110 *
                                     parameters.
                                 12: Invalid subimage specification (no spectral
01111 *
01112 *
                                      axis).
01113 *
                                For returns > 1, a detailed error message is set in
01114 *
                                wcsprm::err if enabled, see wcserr_enable().
01115 *
01116
01117 *
01118 * wcslib_version() - WCSLIB version number
01119 * -
01120 * wcslib version() returns the WCSLIB version number.
01121 *
01122 \star The major version number changes when the ABI changes or when the license
01123 \star conditions change. ABI changes typically result from a change to the 01124 \star contents of one of the structs. The major version number is used to
01125 \star distinguish between incompatible versions of the sharable library.
01126
01127 * The minor version number changes with new functionality or bug fixes that do
```

```
01128 \star not involve a change in the ABI.
01129 :
01130 \star The auxiliary version number (which is often absent) signals changes to the
01131 \star documentation, test suite, build procedures, or any other change that does
01132 \star not affect the compiled library.
01133 >
01134 * Returned:
01135 *
                                                int[3]
                                                                          The broken-down version number:
                        vers[3]
01136 *
                                                                               0: Major version number.
01137 *
                                                                               1: Minor version number.

                                                                              2: Auxiliary version number (zero if absent).
01139 *
                                                                          May be given as a null pointer if not required.
01140 *
01141 * Function return value:
01142 *
                                                char*
                                                                         A null-terminated, statically allocated string
                                                                          containing the version number in the usual form, i.e.
"<major>.<minor>.<auxiliary>".
01143 *
01144 *
01145 *
01146 *
01147 * wcsprm struct - Coordinate transformation parameters
01148 *
01149 \star The wcsprm struct contains information required to transform world
01150 \star coordinates. It consists of certain members that must be set by the user
01151 \star ("given") and others that are set by the WCSLIB routines ("returned").
01152 * While the addresses of the arrays themselves may be set by wcsinit() if it
01153 * (optionally) allocates memory, their contents must be set by the user.
01.154 *
01155 \star Some parameters that are given are not actually required for transforming 01156 \star coordinates. These are described as "auxiliary"; the struct simply provides
01157 \star a place to store them, though they may be used by wcshdo() in constructing a 01158 \star FITS header from a wcsprm struct. Some of the returned values are supplied
01159 \star for informational purposes and others are for internal use only as
01160 * indicated.
01161 *
01162 \star In practice, it is expected that a WCS parser would scan the FITS header to
01163 \star determine the number of coordinate axes. It would then use wcsinit() to 01164 \star allocate memory for arrays in the wcsprm struct and set default values.
01165 * Then as it reread the header and identified each WCS keyrecord it would load
01166 \star the value into the relevant wcsprm array element. This is essentially what
01167 \star wcspih() does - refer to the prologue of wcshdr.h. As the final step,
01168 \star wcsset() is invoked, either directly or indirectly, to set the derived
01169 \star members of the wcsprm struct. wcsset() strips off trailing blanks in all 01170 \star string members and null-fills the character array.
01171 *
01172 *
01173 *
                              (Given and returned) This flag must be set to zero (or 1, see wcsset())
01174 *
                              whenever any of the following wcsprm members are set or changed:
01175 *
01176 *
                                  - wcsprm::naxis (q.v., not normally set by the user),
01177 *
                                  - wcsprm::crpix,
                                  - wcsprm::pc,
01178 *
01179 *
                                  - wcsprm::cdelt,
01180 *
                                  - wcsprm::crval,
01181 *
                                  - wcsprm::cunit,
                                 - wcsprm::ctype,
01182 *
                                  - wcsprm::lonpole,
01183 *
01184 *
                                  - wcsprm::latpole,
01185 *
                                  - wcsprm::restfrq,
01186 *
                                  - wcsprm::restwav,
01187 *
                                  - wcsprm::npv,
01188 *
                                  - wcsprm::pv,
                                  - wcsprm::nps,
01189 *
01190 *
                                  - wcsprm::ps,
01191 *
                                  - wcsprm::cd,
01192 *
                                  - wcsprm::crota,
01193 *
                                  - wcsprm::altlin,
                                 - wcsprm::ntab,
01194 *
01195 *
                                  - wcsprm::nwtb,
01196 *
                                  - wcsprm::tab.
01197 *
                                  - wcsprm::wtb.
01198 *
01199 *
                             This signals the initialization routine, wcsset(), to recompute the
01200 *
                              returned members of the linprm, celprm, spcprm, and tabprm structs.
01201 *
                              wcsset() will reset flag to indicate that this has been done.
01202 *
01203 *
                              PLEASE NOTE: flag should be set to -1 when wcsinit() is called for the
01204 *
                              first time for a particular wcsprm struct in order to initialize memory
01205 *
                              management. It must ONLY be used on the first initialization otherwise
01206 *
                             memory leaks may result.
01207 *
01208 *
                        int naxis
01209 *
                              (Given or returned) Number of pixel and world coordinate elements.
01210 *
01211 *
                              If wcsinit() is used to initialize the linprm struct (as would normally
01212 *
                             be the case) then it will set naxis from the value passed to it as a % \left\{ 1\right\} =\left\{ 1\right
01213 *
                              function argument. The user should not subsequently modify it.
01214 *
```

```
01215 *
         double *crpix
01216 *
            (Given) Address of the first element of an array of double containing
01217 *
            the coordinate reference pixel, CRPIXja.
01218 *
01219 *
          double *pc
            (Given) Address of the first element of the PCi_ja (pixel coordinate)
01220 *
01221 *
            transformation matrix. The expected order is
01222 *
01223 =
              struct wcsprm wcs;
01224 =
              wcs.pc = \{PC1_1, PC1_2, PC2_1, PC2_2\};
01225 *
01226 *
            This may be constructed conveniently from a 2-D array via
01227 *
01228 =
              double m[2][2] = \{ \{PC1_1, PC1_2\}, \}
01229 =
                                 {PC2_1, PC2_2}};
01230 *
01231 *
            which is equivalent to
01232 *
01233 =
              double m[2][2];
01234 =
              m[0][0] = PC1_1;
01235 =
              m[0][1] = PC1_2;
01236 =
              m[1][0] = PC2_1;
01237 =
              m[1][1] = PC2_2;
01238 *
01239 *
            The storage order for this 2-D array is the same as for the 1-D array,
01240 *
            whence
01241 *
01242 =
              wcs.pc = *m;
01243 *
01244 *
            would be legitimate.
01245 *
01246 *
         double *cdelt
01247 *
            (Given) Address of the first element of an array of double containing
01248 *
            the coordinate increments, CDELTia.
01249 *
01250 *
          double *crval
01251 *
            (Given) Address of the first element of an array of double containing
            the coordinate reference values, CRVALia.
01252 *
01253 *
01254 *
          char (*cunit)[72]
01255 *
            (Given) Address of the first element of an array of char[72] containing
01256 *
            the CUNITia keyvalues which define the units of measurement of the
01257 *
            CRVALia, CDELTia, and CDi_ja keywords.
01258 *
01259 *
            As CUNITia is an optional header keyword, cunit[][72] may be left blank
01260 *
            but otherwise is expected to contain a standard units specification as
01261 *
            defined by WCS Paper I. Utility function wcsutrn(), described in
01262 *
            \verb|wcsunits.h|, is available to translate commonly used non-standard units|
            specifications but this must be done as a separate step before invoking
01263 *
01264 *
            wcsset().
01265 *
01266 *
            For celestial axes, if cunit[][72] is not blank, wcsset() uses
            wcsunits() to parse it and scale cdelt[], crval[], and cd[][\star] to degrees. It then resets cunit[][72] to "deg".
01267 *
01268 *
01269 *
01270 *
            For spectral axes, if cunit[][72] is not blank, wcsset() uses wcsunits()
01271 *
            to parse it and scale cdelt[], crval[], and cd[][*] to SI units. It
01272 *
            then resets cunit[][72] accordingly.
01273 *
01274 *
            wcsset() ignores cunit[][72] for other coordinate types; cunit[][72] may
01275 *
           be used to label coordinate values.
01276 *
01277 *
            These variables accomodate the longest allowed string-valued FITS
01278 *
            keyword, being limited to 68 characters, plus the null-terminating
01279 *
            character.
01280 *
01281 *
          char (*ctype)[72]
01282 *
            (Given) Address of the first element of an array of char[72] containing
01283 *
            the coordinate axis types, CTYPEia.
01284 *
01285 *
            The ctype[][72] keyword values must be in upper case and there must be
01286 +
            zero or one pair of matched celestial axis types, and zero or one
01287 *
            spectral axis. The ctype[][72] strings should be padded with blanks on
01288 *
            the right and null-terminated so that they are at least eight characters
01289 *
            in length.
01290 *
01291 *
            These variables accomodate the longest allowed string-valued FITS
01292 *
            keyword, being limited to 68 characters, plus the null-terminating
01293 *
            character.
01294 *
01295 *
          double lonpole
01296 *
            (Given and returned) The native longitude of the celestial pole, phi_p,
01297 *
            given by LONPOLEa [deg] or by PVi_2a [deg] attached to the longitude
01298 *
            axis which takes precedence if defined, and ..
01299 *
          double latpole
01300 *
            (Given and returned) ... the native latitude of the celestial pole,
            theta_p, given by LATPOLEa [deg] or by PVi_3a [deg] attached to the
01301 *
```

```
longitude axis which takes precedence if defined.
01303 *
01304 *
            lonpole and latpole may be left to default to values set by wcsinit()
01305 *
             (see celprm::ref), but in any case they will be reset by wcsset() to
01306 *
            the values actually used. Note therefore that if the wcsprm struct is reused without resetting them, whether directly or via wcsinit(), they
01307 *
01308 +
            will no longer have their default values.
01309 *
01310 *
           double restfrq
01311 *
             (Given) The rest frequency [Hz], and/or \dots
           double restwav
01312 *
             (Given) ... the rest wavelength in vacuo [m], only one of which need be
01313
01314 *
            given, the other should be set to zero.
01315 *
01316 *
01317 *
            (Given) The number of entries in the wcsprm::pv[] array.
01318 *
01319 *
          int npvmax
01320 *
            (Given or returned) The length of the wcsprm::pv[] array.
01321 +
01322 *
            npvmax will be set by wcsinit() if it allocates memory for wcsprm::pv[],
01323 *
             otherwise it must be set by the user. See also wcsnpv().
01324 *
01325 *
          struct pvcard *pv
01326 *
             (Given) Address of the first element of an array of length npvmax of
01327 *
            pycard structs.
01328 *
01329 *
            As a FITS header parser encounters each PVi_ma keyword it should load it
01330 *
             into a pycard struct in the array and increment npv. wcsset()
01331 *
            interprets these as required.
01332 *
01333 *
            Note that, if they were not given, wcsset() resets the entries for
01334 *
             PVi_1a, PVi_2a, PVi_3a, and PVi_4a for longitude axis i to match
01335 *
             phi_0 and theta_0 (the native longitude and latitude of the reference
01336 *
            point), LONPOLEa and LATPOLEa respectively.
01337 *
01338 *
          int nps
01339 *
             (Given) The number of entries in the wcsprm::ps[] array.
01340 *
01341 *
01342 *
             (Given or returned) The length of the wcsprm::ps[] array.
01343 *
            \verb"npsmax" will be set by wcsinit() if it allocates memory for wcsprm::ps[],
01344 *
01345 *
            otherwise it must be set by the user. See also wcsnps().
01346 *
01347 *
01348 *
            (Given) Address of the first element of an array of length npsmax of
            pscard structs.
01349 *
01350 *
01351 *
            As a FITS header parser encounters each PSi ma keyword it should load it
01352 *
             into a pscard struct in the array and increment nps. wcsset()
01353 *
             interprets these as required (currently no PSi_ma keyvalues are
01354 *
             recognized).
01355 *
01356 *
          double *cd
01357 *
             (Given) For historical compatibility, the wcsprm struct supports two
             alternate specifications of the linear transformation matrix, those
01358 *
01359 *
             associated with the CDi_ja keywords, and ...
01360 *
           double *crota
01361 *
             (Given) \dots those associated with the CROTAi keywords. Although these
            may not formally co-exist with PCi_ja, the approach taken here is simply to ignore them if given in conjunction with PCi_ja.
01362 *
01363 *
01364 *
01365 *
01366 *
             (Given) altlin is a bit flag that denotes which of the PCi_ja, CDi_ja
01367 *
            and CROTAi keywords are present in the header:
01368 *
01369 *
            - Bit 0: PCi ja is present.
01370 *
01371 *
             - Bit 1: CDi_ja is present.
01372 *
01373 +
               Matrix elements in the IRAF convention are equivalent to the product
01374 *
               CDi_ja = CDELTia * PCi_ja, but the defaults differ from that of the
               PCi_ja matrix. If one or more CDi_ja keywords are present then all unspecified CDi_ja default to zero. If no CDi_ja (or CROTAi) keywords
01375 *
01376 *
01377 *
               are present, then the header is assumed to be in PCi_ja form whether
01378 *
               or not any PCi_ja keywords are present since this results in an
01379 *
               interpretation of CDELTia consistent with the original FITS
               specification.
01380 *
01381 *
               While CDi_ja may not formally co-exist with PCi_ja, it may co-exist
01382 *
               with CDELTia and CROTAi which are to be ignored.
01383 *
01384 *
01385 *
             - Bit 2: CROTAi is present.
01386 *
               In the AIPS convention, CROTAi may only be associated with the latitude axis of a celestial axis pair. It specifies a rotation in
01387 *
01388 *
```

```
the image plane that is applied AFTER the CDELTia; any other CROTAi
01390 *
               keywords are ignored.
01391 *
01392 *
               CROTAi may not formally co-exist with PCi_ja.
01393 *
01394 *
               CROTAi and CDELTia may formally co-exist with CDi ja but if so are to
01395 *
              be ignored.
01396 *
01397 *
             - Bit 3: PCi_ja + CDELTia was derived from CDi_ja by wcspcx().
01398 *
01399 *
               This bit is set by wcspcx() when it derives PCi_ja and CDELTia from
01400 *
               CDi ja via an orthonormal decomposition. In particular, it signals
01401 *
               wcsset() not to replace PCi_ja by a copy of CDi_ja with CDELTia set
01402 *
               to unity.
01403 *
01404 *
            \texttt{CDi\_ja} \ \texttt{and} \ \texttt{CROTAi} \ \texttt{keywords,} \ \texttt{if found,} \ \texttt{are to be stored in the wcsprm::cd}
01405 *
             and wcsprm::crota arrays which are dimensioned similarly to wcsprm::pc
            and wcsprm::cdelt. FITS header parsers should use the following
01406 *
01407 *
            procedure:
01408
01409 *
            - Whenever a PCi ja keyword is encountered: altlin |= 1;
01410 *
01411 *
            - Whenever a CDi_ja keyword is encountered: altlin |= 2;
01412 *
01413 *
            - Whenever a CROTAi keyword is encountered: altlin |= 4;
01414 *
01415 *
            If none of these bits are set the PCi_ja representation results, i.e.
01416 *
            wcsprm::pc and wcsprm::cdelt will be used as given.
01417 *
01418 *
            These alternate specifications of the linear transformation matrix are
01419 *
             translated immediately to PCi_ja by wcsset() and are invisible to the
            lower-level WCSLIB routines. In particular, unless bit 3 is also swcsset() resets wcsprm::cdelt to unity if CDi_ja is present (and no
01420 *
                                             In particular, unless bit 3 is also set,
01421 *
01422 *
            PCi_ja).
01423 *
            If CROTAi are present but none is associated with the latitude \ensuremath{\mathtt{axis}}
01424 *
01425 *
            (and no PCi_ja or CDi_ja), then wcsset() reverts to a unity PCi_ja
01426 *
            matrix.
01427 *
01428 *
          int velref
01429 *
             (Given) AIPS velocity code VELREF, refer to spcaips().
01430 *
01431 *
             It is not necessary to reset the wcsprm struct (via wcsset()) when
01432 *
            wcsprm::velref is changed.
01433 >
01434 *
          char alt[4]
01435 *
            (Given, auxiliary) Character code for alternate coordinate descriptions
             (i.e. the ^{\prime}a^{\prime} in keyword names such as CTYPEia). This is blank for the
01436 *
            primary coordinate description, or one of the 26 upper-case letters,
01437 *
01438 *
01439 *
01440 *
            An array of four characters is provided for alignment purposes, only the
01441 *
            first is used.
01442 *
01443 *
            It is not necessary to reset the wcsprm struct (via wcsset()) when
01444 *
            wcsprm::alt is changed.
01445 *
01446 *
            (Given, auxiliary) Where the coordinate representation is associated
01447 *
01448 *
            with an image-array column in a FITS binary table, this variable may be
01449 *
            used to record the relevant column number.
01450 *
01451 *
            It should be set to zero for an image header or pixel list.
01452 *
01453 *
            It is not necessary to reset the wcsprm struct (via wcsset()) when
01454 *
            wcsprm::colnum is changed.
01455 *
01456 *
          int *colax
01457 *
            (Given, auxiliary) Address of the first element of an array of int
01458 *
            recording the column numbers for each axis in a pixel list.
01459 *
01460 *
            The array elements should be set to zero for an image header or image
01461 *
            array in a binary table.
01462 *
01463 *
            It is not necessary to reset the wcsprm struct (via wcsset()) when
            wcsprm::colax is changed.
01464 *
01465 *
01466 *
          char (*cname) [72]
01467 *
             (Given, auxiliary) The address of the first element of an array of
01468 *
            char[72] containing the coordinate axis names, CNAMEia.
01469 *
01470 *
             These variables accomodate the longest allowed string-valued FITS
             keyword, being limited to 68 characters, plus the null-terminating
01471 *
01472 *
            character.
01473 *
01474 *
            It is not necessary to reset the wcsprm struct (via wcsset()) when
01475 *
            wcsprm::cname is changed.
```

```
01476 *
01477 *
          double *crder
01478 *
            (Given, auxiliary) Address of the first element of an array of double
01479 *
            recording the random error in the coordinate value, CRDERia.
01480 *
01481 *
            It is not necessary to reset the wcsprm struct (via wcsset()) when
            wcsprm::crder is changed.
01482 *
01483 *
01484 *
          double *csyer
01485 *
            (Given, auxiliary) Address of the first element of an array of double
01486 *
            recording the systematic error in the coordinate value, CSYERia.
01487 *
01488 *
            It is not necessary to reset the wcsprm struct (via wcsset()) when
01489 *
            wcsprm::csyer is changed.
01490 *
01491 *
          double *czphs
            (Given, auxiliary) Address of the first element of an array of double recording the time at the zero point of a phase axis, CZPHSia.
01492 *
01493 *
01494 *
01495 *
            It is not necessary to reset the wcsprm struct (via wcsset()) when
01496 *
            wcsprm::czphs is changed.
01497 *
01498 *
          double *cperi
01499 *
            (Given, auxiliary) Address of the first element of an array of double
01500 *
            recording the period of a phase axis, CPERIia.
01501 *
01.502 *
            It is not necessary to reset the wcsprm struct (via wcsset()) when
01503 *
            wcsprm::cperi is changed.
01504 *
01505 *
          char wcsname[72]
01506 *
            (Given, auxiliary) The name given to the coordinate representation,
01507 *
            WCSNAMEa. This variable accommodates the longest allowed string-valued
01508 *
            FITS keyword, being limited to 68 characters, plus the null-terminating
01509 *
            character.
01510 *
01511 *
            It is not necessary to reset the wcsprm struct (via wcsset()) when
01512 *
            wcsprm::wcsname is changed.
01513 *
01514 *
          char timesvs[72]
01515 *
            (Given, auxiliary) TIMESYS keyvalue, being the time scale (UTC, TAI,
01516 *
            etc.) in which all other time-related auxiliary header values are
01517 *
            recorded. Also defines the time scale for an image axis with CTYPEia
            set to 'TIME'.
01518 *
01519 *
01520 *
            It is not necessary to reset the wcsprm struct (via wcsset()) when
01521 *
            wcsprm::timesys is changed.
01522 *
01523 *
          char trefpos[72]
01524 *
            (Given, auxiliary) TREFPOS keyvalue, being the location in space where
01525 *
            the recorded time is valid.
01526 *
01527 *
            It is not necessary to reset the wcsprm struct (via wcsset()) when
01528 *
            wcsprm::trefpos is changed.
01529 *
01530 *
          char trefdir[72]
            (Given, auxiliary) TREFDIR keyvalue, being the reference direction used
01531 *
01532 *
            in calculating a pathlength delay.
01533 *
01534 *
            It is not necessary to reset the wcsprm struct (via wcsset()) when
01535 *
            wcsprm::trefdir is changed.
01536 *
01537 *
          char plephem[72]
01538 *
            (Given, auxiliary) PLEPHEM keyvalue, being the Solar System ephemeris
01539 *
            used for calculating a pathlength delay.
01540 *
01541 *
            It is not necessary to reset the wcsprm struct (via wcsset()) when
01542 *
            wcsprm::plephem is changed.
01543 *
01544 *
          char timeunit[72]
            (Given, auxiliary) TIMEUNIT keyvalue, being the time units in which
01546 *
            the following header values are expressed: TSTART, TSTOP, TIMEOFFS,
01547 *
            TIMSYER, TIMRDER, TIMEDEL. It also provides the default value for
01548 *
            CUNITia for time axes.
01549 *
01550 *
            It is not necessary to reset the wcsprm struct (via wcsset()) when
01551 *
            wcsprm::timeunit is changed.
01552 *
01553 *
            (Given, auxiliary) DATEREF keyvalue, being the date of a reference epoch
01554 *
01555 *
            relative to which other time measurements refer.
01556 *
            It is not necessary to reset the wcsprm struct (via wcsset()) when
01558 *
            wcsprm::dateref is changed.
01559 *
01560 *
          double mjdref[2]
            (Given, auxiliary) MJDREF keyvalue, equivalent to DATEREF expressed as a Modified Julian Date (MJD = JD - 2400000.5). The value is given as
01561 *
01562 *
```

```
the sum of the two-element vector, allowing increased precision.
01564 *
01565 *
            It is not necessary to reset the wcsprm struct (via wcsset()) when
01566 *
            wcsprm::mjdref is changed.
01567 *
01568 *
          double timeoffs
01569 *
            (Given, auxiliary) TIMEOFFS keyvalue, being a time offset, which may be
01570 *
            used, for example, to provide a uniform clock correction for times
01571 *
            referenced to DATEREF.
01572 *
01573 *
            It is not necessary to reset the wcsprm struct (via wcsset()) when
01574 *
            wcsprm::timeoffs is changed.
01575 *
01576 *
          char dateobs[72]
01577 *
             (Given, auxiliary) DATE-OBS keyvalue, being the date at the start of the
01578 *
             observation unless otherwise explained in the DATE-OBS keycomment, in
01579 *
            ISO format, yyyy-mm-ddThh:mm:ss.
01580 *
01581 *
            It is not necessary to reset the wcsprm struct (via wcsset()) when
01582
            wcsprm::dateobs is changed.
01583 *
01584 *
          char datebeg[72]
            (Given, auxiliary) DATE-BEG keyvalue, being the date at the start of the
01585 *
01586 *
            observation in ISO format, yyyy-mm-ddThh:mm:ss.
01587 *
01588 *
             It is not necessary to reset the wcsprm struct (via wcsset()) when
01589 *
            wcsprm::datebeg is changed.
01590 *
01591 *
          char dateavg[72]
01592 *
            (Given, auxiliary) DATE-AVG keyvalue, being the date at a representative
01593 *
            mid-point of the observation in ISO format, vvvv-mm-ddThh:mm:ss.
01594 *
01595 *
             It is not necessary to reset the wcsprm struct (via wcsset()) when
01596 *
            wcsprm::dateavg is changed.
01597 *
01598 *
          char dateend[72]
01599 *
            (Given, auxiliary) DATE-END keyvalue, baing the date at the end of the
01600 *
            observation in ISO format, yyyy-mm-ddThh:mm:ss.
01601 *
01602 *
             It is not necessary to reset the wcsprm struct (via wcsset()) when
01603 *
            wcsprm::dateend is changed.
01604 *
01605 *
          double midobs
            (Given, auxiliary) MJD-OBS keyvalue, equivalent to DATE-OBS expressed as a Modified Julian Date (MJD = JD - 2400000.5).
01606 *
01607 *
01608 *
01609 *
            It is not necessary to reset the wcsprm struct (via wcsset()) when
01610 *
            wcsprm::mjdobs is changed.
01611 *
01612 *
          double midbeg
            (Given, auxiliary) MJD-BEG keyvalue, equivalent to DATE-BEG expressed as a Modified Julian Date (MJD = JD - 2400000.5).
01613 *
01614 *
01615 *
01616 *
            It is not necessary to reset the wcsprm\ struct\ (via\ wcsset())\ when
01617 *
            wcsprm::mjdbeg is changed.
01618 *
01619 *
          double mjdavg
            (Given, auxiliary) MJD-AVG keyvalue, equivalent to DATE-AVG expressed as a Modified Julian Date (MJD = JD - 2400000.5).
01620 *
01621 *
01622 *
01623 *
            It is not necessary to reset the wcsprm struct (via wcsset()) when
01624 *
            wcsprm::mjdavg is changed.
01625 *
01626 *
          double mjdend
01627 *
            (Given, auxiliary) MJD-END keyvalue, equivalent to DATE-END expressed
01628 *
            as a Modified Julian Date (MJD = JD - 2400000.5).
01629 *
01630 *
            It is not necessary to reset the wcsprm struct (via wcsset()) when
01631 *
            wcsprm::midend is changed.
01632 *
01633 *
          double jepoch
01634 *
            (Given, auxiliary) JEPOCH keyvalue, equivalent to DATE-OBS expressed
            as a Julian epoch.
01635 *
01636 *
01637 *
            It is not necessary to reset the wcsprm struct (via wcsset()) when
            wcsprm::jepoch is changed.
01638 *
01639 *
01640 *
          double bepoch
01641 *
            (Given, auxiliary) BEPOCH keyvalue, equivalent to DATE-OBS expressed
01642 *
            as a Besselian epoch
01643 *
01644 *
            It is not necessary to reset the wcsprm struct (via wcsset()) when
            wcsprm::bepoch is changed.
01645 *
01646 *
01647 *
          double tstart
            (Given, auxiliary) TSTART keyvalue, equivalent to DATE-BEG expressed
01648 *
01649 *
            as a time in units of TIMEUNIT relative to DATEREF+TIMEOFFS.
```

```
01651 *
            It is not necessary to reset the wcsprm struct (via wcsset()) when
01652 *
            wcsprm::tstart is changed.
01653 *
          double tstop
01654 *
01655 *
            (Given, auxiliary) TSTOP keyvalue, equivalent to DATE-END expressed
            as a time in units of TIMEUNIT relative to DATEREF+TIMEOFFS.
01656
01657 *
            It is not necessary to reset the wcsprm struct (via wcsset()) when
01658 *
01659 *
            wcsprm::tstop is changed.
01660 *
01661 *
          double xposure
            (Given, auxiliary) XPOSURE keyvalue, being the effective exposure time
01662 *
01663 *
            in units of TIMEUNIT.
01664 *
            It is not necessary to reset the wcsprm\ struct\ (via\ wcsset())\ when
01665 *
01666 *
            wcsprm::xposure is changed.
01667 *
01668 *
          double telapse
            (Given, auxiliary) TELAPSE keyvalue, equivalent to the elapsed time
01669 *
01670 *
            between DATE-BEG and DATE-END, in units of TIMEUNIT.
01671 *
01672 *
            It is not necessary to reset the wcsprm struct (via wcsset()) when
01673 *
            wcsprm::telapse is changed.
01674 *
01675 *
          double timsyer
01676 *
            (Given, auxiliary) TIMSYER keyvalue, being the absolute error of the
01677 *
           time values, in units of TIMEUNIT.
01678 *
01679 *
            It is not necessary to reset the wcsprm struct (via wcsset()) when
01680 *
           wcsprm::timsver is changed.
01681 *
01682 *
          double timrder
01683 *
            (Given, auxiliary) TIMRDER keyvalue, being the accuracy of time stamps
01684 *
           relative to each other, in units of TIMEUNIT.
01685 *
01686 *
            It is not necessary to reset the wcsprm struct (via wcsset()) when
            wcsprm::timrder is changed.
01687 *
01688 *
01689 *
          double timedel
01690 *
            (Given, auxiliary) TIMEDEL keyvalue, being the resolution of the time
01691 *
           stamps.
01692 *
01693 *
            It is not necessary to reset the wcsprm struct (via wcsset()) when
01694 *
            wcsprm::timedel is changed.
01695 *
01696 *
          double timepixr
            (Given, auxiliary) TIMEPIXR keyvalue, being the relative position of the
01697 *
01698 *
            time stamps in binned time intervals, a value between 0.0 and 1.0.
01699 *
01700 *
            It is not necessary to reset the wcsprm struct (via wcsset()) when
01701 *
            wcsprm::timepixr is changed.
01702 *
01703 *
          double obsgeo[6]
            (Given, auxiliary) Location of the observer in a standard terrestrial
01704 *
01705 *
            reference frame. The first three give ITRS Cartesian coordinates
            OBSGEO-X [m], OBSGEO-Y [m], OBSGEO-Z [m], and the second three give
01706 *
01707 *
            OBSGEO-L [deg], OBSGEO-B [deg], OBSGEO-H [m], which are related through
01708 *
            a standard transformation.
01709 *
01710 *
            It is not necessary to reset the wcsprm struct (via wcsset()) when
01711 *
           wcsprm::obsgeo is changed.
01712 *
01713 *
01714 *
            (Given, auxiliary) OBSORBIT keyvalue, being the URI, URL, or name of an
01715 *
           orbit ephemeris file giving spacecraft coordinates relating to TREFPOS.
01716 *
01717 *
            It is not necessary to reset the wcsprm struct (via wcsset()) when
01718 *
            wcsprm::obsorbit is changed.
01719 *
01720 *
          char radesys[72]
01721 *
            (Given, auxiliary) The equatorial or ecliptic coordinate system type,
01722 *
           RADESYSa.
01723 *
01724 *
            It is not necessary to reset the wcsprm struct (via wcsset()) when
01725 *
            wcsprm::radesys is changed.
01726 *
01727 *
            (Given, auxiliary) The equinox associated with dynamical equatorial or
01728 *
            ecliptic coordinate systems, EQUINOXa (or EPOCH in older headers). Not applicable to ICRS equatorial or ecliptic coordinates.
01729 *
01730 *
01731 >
01732 *
            It is not necessary to reset the wcsprm struct (via wcsset()) when
01733 *
            wcsprm::equinox is changed.
01734 *
01735 *
          char specsys[72]
01736 *
            (Given, auxiliary) Spectral reference frame (standard of rest),
```

```
01737 *
            SPECSYSa.
01738 *
01739 *
            It is not necessary to reset the wcsprm struct (via wcsset()) when
01740 *
            wcsprm::specsys is changed.
01741 *
01742 *
          char ssvsobs[72]
01743 *
             (Given, auxiliary) The spectral reference frame in which there is no
01744 *
             differential variation in the spectral coordinate across the
01745 *
             field-of-view, SSYSOBSa.
01746 *
01747 *
             It is not necessary to reset the wcsprm struct (via wcsset()) when
01748 *
             wcsprm::ssysobs is changed.
01749 *
01750 *
          double velosys
01751 *
             (Given, auxiliary) The relative radial velocity [m/s] between the
01752 *
             observer and the selected standard of rest in the direction of the
01753 *
             celestial reference coordinate, VELOSYSa.
01754 *
01755 *
            It is not necessary to reset the wcsprm struct (via wcsset()) when
01756 *
            wcsprm::velosys is changed.
01757 *
01758 *
          double zsource
01759 *
            (Given, auxiliary) The redshift, ZSOURCEa, of the source.
01760 *
01761 *
             It is not necessary to reset the wcsprm struct (via wcsset()) when
01762 *
            wcsprm::zsource is changed.
01763 *
01764 *
          char ssyssrc[72]
01765 *
             (Given, auxiliary) The spectral reference frame (standard of rest),
01766 *
            SSYSSRCa, in which wcsprm::zsource was measured.
01767 *
01768 *
             It is not necessary to reset the wcsprm struct (via wcsset()) when
01769 *
             wcsprm::ssyssrc is changed.
01770 *
01771 *
          double velangl
01772 *
             (Given, auxiliary) The angle [deg] that should be used to decompose an
01773 *
             observed velocity into radial and transverse components.
01774 *
01775 *
             It is not necessary to reset the wcsprm struct (via wcsset()) when
01776 *
            wcsprm::velangl is changed.
01777 *
01778 *
          struct auxprm *aux
            (Given, auxiliary) This struct holds auxiliary coordinate system information of a specialist nature. While these parameters may be widely recognized within particular fields of astronomy, they differ
01779 *
01780 *
01781 *
             from the above auxiliary parameters in not being defined by any of the
01782 *
01783 *
            FITS WCS standards. Collecting them together in a separate struct that
01784 *
             is allocated only when required helps to control bloat in the size of
01785 *
            the wcsprm struct.
01786 *
01787 *
          int ntab
01788 *
            (Given) See wcsprm::tab.
01789 *
01790 *
          int nwtb
01791 *
             (Given) See wcsprm::wtb.
01792 *
01793 *
          struct tabprm *tab
01794 *
             (Given) Address of the first element of an array of ntab tabprm structs
01795 *
             for which memory has been allocated. These are used to store tabular
01796 *
             transformation parameters.
01797 *
01798 *
            Although technically wcsprm::ntab and tab are "given", they will
01799 *
            normally be set by invoking wcstab(), whether directly or indirectly.
01800 *
            The tabprm structs contain some members that must be supplied and others
01801 *
01802 *
            that are derived. The information to be supplied comes primarily from
01803 *
            arrays stored in one or more FITS binary table extensions. These arrays, referred to here as "wcstab arrays", are themselves located by
01804 *
01805 *
            parameters stored in the FITS image header.
01806 *
01807 *
          struct wtbarr *wtb
01808 *
             (Given) Address of the first element of an array of nwtb wtbarr structs
01809 *
             for which memory has been allocated. These are used in extracting
01810 *
             wcstab arrays from a FITS binary table.
01811 *
01812 *
            Although technically wcsprm::nwtb and wtb are "given", they will
01813 *
            normally be set by invoking wcstab(), whether directly or indirectly.
01814 *
01815 *
          char lngtyp[8]
01816 *
             (Returned) Four-character WCS celestial longitude and ...
01817 *
           char lattyp[8]
             (Returned) ... latitude axis types. e.g. "RA", "DEC", "GLON", "GLAT", etc. extracted from 'RA--', 'DEC-', 'GLON', 'GLAT', etc. in the first
01818 *
01819 *
             four characters of CTYPEia but with trailing dashes removed.
01820 *
01821 *
            as char[8] for alignment reasons.)
01822 *
01823 *
          int lng
```

```
01824 *
            (Returned) Index for the longitude coordinate, and ...
01825 *
01826 *
            (Returned) ... index for the latitude coordinate, and ...
01827 *
          int spec
01828 *
            (Returned) ... index for the spectral coordinate, and ...
01829 *
          int time
01830 *
            (Returned) ... index for the time coordinate in the imgcrd[][] and
01831 *
            world[][] arrays in the API of wcsp2s(), wcss2p() and wcsmix().
01832 *
01833 *
            These may also serve as indices into the pixcrd[][] array provided that
01834 *
           the PCi_ja matrix does not transpose axes.
01835 *
01836 *
          int cubeface
01837 *
            (Returned) Index into the pixcrd[][] array for the CUBEFACE axis. This
01838 *
            is used for quadcube projections where the cube faces are stored on a
01839 *
            separate axis (see wcs.h).
01840 *
01841 *
         int chksum
01842 *
            (Returned) Checksum of keyvalues provided (see wcsprm::flag). Used by
01843
            wcsenq() to validate the self-consistency of the struct. Note that
01844 *
            the checksum incorporates addresses and is therefore highly specific to
01845 *
            the instance of the wcsprm struct.
01846 *
01847 *
01848 *
            (Returned) Address of the first element of an array of int containing a
01849 *
            four-digit type code for each axis.
01.850 *
01851 *
            - First digit (i.e. 1000s):
01852 *
              - 0: Non-specific coordinate type.
              - 1: Stokes coordinate.
01853 *
01854 *
              - 2: Celestial coordinate (including CUBEFACE).
01855 *
              - 3: Spectral coordinate.
01856 *
              - 4: Time coordinate.
01857 *
01858 *
           - Second digit (i.e. 100s):
01859 *
              - 0: Linear axis.
              - 1: Quantized axis (STOKES, CUBEFACE).
01860 *
01861 *
              - 2: Non-linear celestial axis.
01862 *
              - 3: Non-linear spectral axis.
01863 *
              - 4: Logarithmic axis.
01864 *
              - 5: Tabular axis.
01865 *
            - Third digit (i.e. 10s):
01866 *
01867 *
              - 0: Group number, e.g. lookup table number, being an index into the
                   tabprm array (see above).
01868 *
01869 *
01870 *
            - The fourth digit is used as a qualifier depending on the axis type.
01871 *
01872 *
              - For celestial axes:
01873 *
                - 0: Longitude coordinate.
01874 *
                - 1: Latitude coordinate.
01875 *
                - 2: CUBEFACE number.
01876 *
01877 *
              - For lookup tables: the axis number in a multidimensional table.
01878 *
01879 *
            CTYPEia in "4-3" form with unrecognized algorithm code will have its
            type set to -1 and generate an error.
01880 *
01881 *
01882 *
         struct linprm lin
01883 *
            (Returned) Linear transformation parameters (usage is described in the
01884 *
            prologue to lin.h).
01885 *
01886 *
         struct celprm cel
01887 *
            (Returned) Celestial transformation parameters (usage is described in
01888 *
            the prologue to cel.h).
01889 *
01890 *
01891 *
            (Returned) Spectral transformation parameters (usage is described in the
01892 *
            prologue to spc.h).
01893 *
01894 *
          struct wcserr *err
01895 *
            (Returned) If enabled, when an error status is returned, this struct
01896 *
           contains detailed information about the error, see wcserr_enable().
01897 *
01898 *
         int m flag
01899 *

01937 *
01938 *
01939 *
01940 * pvcard struct - Store for PVi_ma keyrecords
01941 *
01942 \star The pycard struct is used to pass the parsed contents of PVi_ma keyrecords
01943 * to wcsset() via the wcsprm struct.
01944 *
01945 \star All members of this struct are to be set by the user.
01946 *
01947 *
         int i
01948 *
           (Given) Axis number (1-relative), as in the FITS PVi_ma keyword. If
01949 *
           i == 0, wcsset() will replace it with the latitude axis number.
01950 *
01951 *
01952 *
           (Given) Parameter number (non-negative), as in the FITS PVi_ma keyword.
01953 *
01954 *
         double value
01955 *
           (Given) Parameter value.
01956 *
01957 *
01958 * pscard struct - Store for PSi_ma keyrecords
01959 *
01960 * The pscard struct is used to pass the parsed contents of PSi_ma keyrecords
01961 * to wcsset() via the wcsprm struct.
01962 *
01963 \star All members of this struct are to be set by the user.
01964 *
01965 *
01966 *
           (Given) Axis number (1-relative), as in the FITS PSi ma keyword.
01967 *
01968 *
01969 *
           (Given) Parameter number (non-negative), as in the FITS PSi_ma keyword.
01970 *
01971 *
         char value[72]
01972 *
           (Given) Parameter value.
01973 *
01974 *
01975 * auxprm struct - Additional auxiliary parameters
01976 *
01977 \star The auxprm struct holds auxiliary coordinate system information of a
01978 \star specialist nature. It is anticipated that this struct will expand in future
01979 * to accomodate additional parameters.
01981 \star All members of this struct are to be set by the user.
01982 *
01983 *
         double rsun_ref
01984 *
            (Given, auxiliary) Reference radius of the Sun used in coordinate
            calculations (m).
01985 *
01986 *
01987 *
         double dsun_obs
           (Given, auxiliary) Distance between the centre of the Sun and the
01988 *
01989 *
            observer (m).
01990 *
01991 *
          double crln obs
01992 *
            (Given, auxiliary) Carrington heliographic longitude of the observer
01993 *
            (deg).
01994 *
01995 *
          double hgln_obs
            (Given, auxiliary) Stonyhurst heliographic longitude of the observer
01996 *
01997 *
            (dea).
```

```
01998 *
01999 *
          double halt obs
02000 *
            (Given, auxiliary) Heliographic latitude (Carrington or Stonyhurst) of
02001 *
           the observer (deg).
02002 *
02003 *
         double a radius
02004 *
          Length of the semi-major axis of a triaxial ellipsoid approximating the
02005 *
            shape of a body (e.g. planet) in the solar system (m).
02006 *
02007 *
          Length of the intermediate axis, normal to the semi-major and semi-minor
02008 *
02009 *
            axes, of a triaxial ellipsoid approximating the shape of a body \ensuremath{(m)}\,.
02010 *
02011 *
02012 *
            Length of the semi-minor axis, normal to the semi-major axis, of a
02013 *
            triaxial ellipsoid approximating the shape of a body (m).
02014 *
02015 *
         double blon obs
02016 *
          Bodycentric longitude of the observer in the coordinate system fixed to
02017 *
           the planet or other solar system body (deg, in range 0 to 360).
02018 *
02019 *
         double blat_obs
          Bodycentric latitude of the observer in the coordinate system fixed to
02020 *
02021 *
           the planet or other solar system body (deg).
02022 *
02023 *
         double bdis_obs
02024 *
           Bodycentric distance of the observer (m).
02025 *
02026 *
02027 * Global variable: const char *wcs_errmsq[] - Status return messages
02028 * -----
02029 \star Error messages to match the status value returned from each function.
02030 *
02031 *==

6.25 wcserr.h File Reference

Data Structures

struct wcserr

Error message handling.

Macros

- #define ERRLEN (sizeof(struct wcserr)/sizeof(int))
- #define WCSERR SET(status) err, status, function, FILE , LINE

Fill in the contents of an error object.

Functions

• int wcserr enable (int enable)

Enable/disable error messaging.

• int wcserr size (const struct wcserr *err, int sizes[2])

Compute the size of a wcserr struct.

int wcserr_prt (const struct wcserr *err, const char *prefix)

Print a wcserr struct.

int wcserr clear (struct wcserr **err)

Clear a wcserr struct.

 int wcserr_set (struct wcserr **err, int status, const char *function, const char *file, int line_no, const char *format,...)

Fill in the contents of an error object.

int wcserr_copy (const struct wcserr *src, struct wcserr *dst)

Copy an error object.

6.25.1 Detailed Description

Most of the structs in WCSLIB contain a pointer to a wcserr struct as a member. Functions in WCSLIB that return an error status code can also allocate and set a detailed error message in this struct, which also identifies the function, source file, and line number where the error occurred.

For example:

```
struct prjprm prj;
wcserr_enable(1);
if (prjini(&prj)) {
    // Print the error message to stderr.
    wcsprintf_set(stderr);
    wcserr_prt(prj.err, 0x0);
}
```

A number of utility functions used in managing the wcserr struct are for **internal use only**. They are documented here solely as an aid to understanding the code. They are not intended for external use - the API may change without notice!

6.25.2 Macro Definition Documentation

ERRLEN

```
#define ERRLEN (sizeof(struct wcserr)/sizeof(int))
```

WCSERR_SET

Fill in the contents of an error object.

INTERNAL USE ONLY.

WCSERR_SET() is a preprocessor macro that helps to fill in the argument list of wcserr_set(). It takes status as an argument of its own and provides the name of the source file and the line number at the point where invoked. It assumes that the err and function arguments of wcserr_set() will be provided by variables of the same names.

6.25.3 Function Documentation

wcserr enable()

Enable/disable error messaging.

wcserr_enable() enables or disables wcserr error messaging. By default it is disabled.

PLEASE NOTE: This function is not thread-safe.

Parameters

in	enable	If true (non-zero), enable error messaging, else disable it.
----	--------	--

Returns

Status return value:

- 0: Error messaging is disabled.
- 1: Error messaging is enabled.

wcserr_size()

Compute the size of a wcserr struct.

wcserr_size() computes the full size of a wcserr struct, including allocated memory.

Parameters

in	err	The error object. If NULL, the base size of the struct and the allocated size are both set to zero.
out	sizes	The first element is the base size of the struct as returned by sizeof(struct wcserr). The
Generated o	n Tue May	second element is the total allocated size of the message buffer, in bytes.

Returns

Status return value:

• 0: Success.

wcserr_prt()

Print a wcserr struct.

wcserr_prt() prints the error message (if any) contained in a wcserr struct. It uses the wcsprintf() functions.

Parameters

in	err	The error object. If NULL, nothing is printed.
in	prefix	If non-NULL, each output line will be prefixed with this string.

Returns

Status return value:

- 0: Success.
- 2: Error messaging is not enabled.

wcserr_clear()

Clear a wcserr struct.

wcserr_clear() clears (deletes) a wcserr struct.

Parameters

in,out	err	The error object. If NULL, nothing is done. Set to NULL on return.
--------	-----	--

Returns

Status return value:

• 0: Success.

wcserr_set()

```
int wcserr_set (
          struct wcserr ** err,
```

```
int status,
const char * function,
const char * file,
int line_no,
const char * format,
... )
```

Fill in the contents of an error object.

INTERNAL USE ONLY.

wcserr_set() fills a wcserr struct with information about an error.

A convenience macro, WCSERR_SET, provides the source file and line number information automatically.

Parameters

in,out	err	Error object. If err is NULL, returns the status code given without setting an error message. If *err is NULL, allocates memory for a wcserr struct (provided that status is non-zero).
in	status	Numeric status code to set. If 0, then *err will be deleted and *err will be returned as NULL.
in	function	Name of the function generating the error. This must point to a constant string, i.e. in the initialized read-only data section ("data") of the executable.
in	file	Name of the source file generating the error. This must point to a constant string, i.e. in the initialized read-only data section ("data") of the executable such as given by theFILE preprocessor macro.
in	line_no	Line number in the source file generating the error such as given by theLINE preprocessor macro.
in	format	Format string of the error message. May contain printf-style %-formatting codes.
in		The remaining variable arguments are applied (like printf) to the format string to generate the error message.

Returns

The status return code passed in.

wcserr_copy()

Copy an error object.

INTERNAL USE ONLY.

wcserr_copy() copies one error object to another. Use of this function should be avoided in general since the function, source file, and line number information copied to the destination may lose its context.

Parameters

in	src	Source error object. If src is NULL, dst is cleared.
out	dst	Destination error object. If NULL, no copy is made.

Returns

Numeric status code of the source error object.

00024 *=====
00025 *
00026 \star WCSLIB 8.3 - C routines that implement the FITS World Coordinate System
00027 \star (WCS) standard. Refer to the README file provided with WCSLIB for an 00028 \star overview of the library.
00029 *
00030 * Summary of the weserr routines
00031 *
00032 \star Most of the structs in WCSLIB contain a pointer to a wcserr struct as a
00033 \star member. Functions in WCSLIB that return an error status code can also
00034 \star allocate and set a detailed error message in this struct, which also
00035 \star identifies the function, source file, and line number where the error
00036 * occurred.
00037 *
00038 * For example:
00039 *
00040 =
             struct prjprm prj;
00041 =
             wcserr_enable(1);
00042 =
            if (prjini(&prj)) {
              // Print the error message to stderr.
wcsprintf_set(stderr);
00043 =
00044 =
00045 =
              wcserr_prt(prj.err, 0x0);
00046 =
00047 *
00048 \star A number of utility functions used in managing the wcserr struct are for 00049 \star internal use only. They are documented here solely as an aid to 00050 \star understanding the code. They are not intended for external use – the API
00051 * may change without notice!
00052 *
00053 *
00054 * wcserr struct - Error message handling
00055 *
00056 \star The wcserr struct contains the numeric error code, a textual description of
00057 \star the error, and information about the function, source file, and line number
00058 \star where the error was generated.
00059 +
00060 *
          int status
00061 *
            Numeric status code associated with the error, the meaning of which
00062 *
             depends on the function that generated it. See the documentation for
00063 *
            the particular function.
00064 *
00065 *
          int line_no
00066 *
            Line number where the error occurred as given by the __LINE__
00067 *
           preprocessor macro.
00068 *
00069 *
          const char *function
00070 *
            Name of the function where the error occurred.
00071 *
00072 *
           const char *file
            Name of the source file where the error occurred as given by the
00073 *
00074 *
            __FILE__ preprocessor macro.
00075 *
00076 *

00162 \star Given and returned:
00163 *
                   struct wcserr**
         err
```

```
Error object.
00165 *
00166 *
                              If err is NULL, returns the status code given without
00167 *
                              setting an error message.
00168 *
                              If *err is NULL, allocates memory for a wcserr struct
00169 *
00170
                              (provided that status is non-zero).
00171 *
00172 * Given:
00173 *
         status
                  int
                              Numeric status code to set. If 0, then \star \mathrm{err} will be
00174 *
                              deleted and *err will be returned as NULL.
00175 *
00176 *
         function const char *
00177 *
                              Name of the function generating the error. This
00178 *
                              must point to a constant string, i.e. in the
00179 *
                              initialized read-only data section ("data") of the
00180 *
                              executable.
00181 *
00182 *
         file
                   const char *
00183 *
                              Name of the source file generating the error. This
00184 *
                              must point to a constant string, i.e. in the
00185 *
                              initialized read-only data section ("data") of the
00186 *
                              executable such as given by the \_\_{FILE}\_\_ preprocessor
00187 *
                              macro.
00188 *
00189 *
         line_no int
                             Line number in the source file generating the error
00190 *
                              such as given by the __LINE__ preprocessor macro.
00191 *
00192 *
          format
                   const char *
                             Format string of the error message. May contain printf-style %-formatting codes.
00193 *
00194 *
00195 *
00196 *
                             The remaining variable arguments are applied (like
00197 *
                              printf) to the format string to generate the error
00198 *
                              message.
00199 *
00200 * Function return value:
                             The status return code passed in.
                   int
00202 *
00203 *
00204 * wcserr_copy() - Copy an error object
00205 *
00206 * INTERNAL USE ONLY.
00207 *
00208 \star wcserr_copy() copies one error object to another. Use of this function
00209 \star should be avoided in general since the function, source file, and line
00210 \star number information copied to the destination may lose its context.
00211 *

                  const struct wcserr*
00214 *
                             Source error object. If src is NULL, dst is cleared.
00215 *
00216 * Returned:
00217 * dst
                   struct wcserr*
00218 *
                              Destination error object. If NULL, no copy is made.
00219 *
00220 * Function return value:
00221 *
                             Numeric status code of the source error object.
00222 *
00223 *
00224 * WCSERR SET() macro - Fill in the contents of an error object
00225 * -
00226 * INTERNAL USE ONLY.
00227 >
00228 \star WCSERR_SET() is a preprocessor macro that helps to fill in the argument list
00229 \star of wcserr_set(). It takes status as an argument of its own and provides the
00230 \star name of the source file and the line number at the point where invoked. It
00231 \star assumes that the err and function arguments of wcserr_set() will be provided
00232 \star by variables of the same names.

Functions

int wcsfix (int ctrl, const int naxis[], struct wcsprm *wcs, int stat[])

Translate a non-standard WCS struct.

• int wcsfixi (int ctrl, const int naxis[], struct wcsprm *wcs, int stat[], struct wcserr info[])

Translate a non-standard WCS struct.

int cdfix (struct wcsprm *wcs)

Fix erroneously omitted CDi_ja keywords.

int datfix (struct wcsprm *wcs)

Translate DATE-OBS and derive MJD-OBS or vice versa.

int obsfix (int ctrl, struct wcsprm *wcs)

complete the OBSGEO-[XYZLBH] vector of observatory coordinates.

int unitfix (int ctrl, struct wcsprm *wcs)

Correct aberrant CUNITia keyvalues.

int spcfix (struct wcsprm *wcs)

Translate AIPS-convention spectral types.

int celfix (struct wcsprm *wcs)

Translate AIPS-convention celestial projection types.

int cylfix (const int naxis[], struct wcsprm *wcs)

Fix malformed cylindrical projections.

int wcspcx (struct wcsprm *wcs, int dopc, int permute, double rotn[2])
 regularize PCi_j.

Variables

const char * wcsfix_errmsg[]
 Status return messages.

6.27.1 Detailed Description

Routines in this suite identify and translate various forms of construct known to occur in FITS headers that violate the FITS World Coordinate System (WCS) standard described in

```
"Representations of world coordinates in FITS",
Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061 (WCS Paper I)

"Representations of celestial coordinates in FITS",
Calabretta, M.R., & Greisen, E.W. 2002, A&A, 395, 1077 (WCS Paper II)

"Representations of spectral coordinates in FITS",
Greisen, E.W., Calabretta, M.R., Valdes, F.G., & Allen, S.L.
2006, A&A, 446, 747 (WCS Paper III)

"Representations of time coordinates in FITS -
Time and relative dimension in space",
Rots, A.H., Bunclark, P.S., Calabretta, M.R., Allen, S.L.,
Manchester, R.N., & Thompson, W.T. 2015, A&A, 574, A36 (WCS Paper VII)
```

Repairs effected by these routines range from the translation of non-standard values for standard WCS keywords, to the repair of malformed coordinate representations. Some routines are also provided to check the consistency of pairs of keyvalues that define the same measure in two different ways, for example, as a date and an MJD.

A separate routine, wcspcx(), "regularizes" the linear transformation matrix component (PCi_j) of the coordinate transformation to make it more human-readable. Where a coordinate description was constructed from CDi_j, it decomposes it into PCi_j + CDELTi in a meaningful way. Optionally, it can also diagonalize the PCi_j matrix (as far as possible), i.e. undo a transposition of axes in the intermediate pixel coordinate system.

Non-standard keyvalues:

AIPS-convention celestial projection types, NCP and GLS, and spectral types, 'FREQ-LSR', 'FELO-HEL', etc., set in CTYPEia are translated on-the-fly by wcsset() but without modifying the relevant ctype[], pv[] or specsys members of the wcsprm struct. That is, only the information extracted from ctype[] is translated when wcsset() fills in wcsprm::cel (celprm struct) or wcsprm::spc (spcprm struct).

On the other hand, these routines do change the values of wcsprm::ctype[], wcsprm::pv[], wcsprm::specsys and other wcsprm struct members as appropriate to produce the same result as if the FITS header itself had been translated.

Auxiliary WCS header information not used directly by WCSLIB may also be translated. For example, the older **DATE-OBS** date format (wcsprm::dateobs) is recast to year-2000 standard form, and MJD-OBS (wcsprm::mjdobs) will be deduced from it if not already set.

Certain combinations of keyvalues that result in malformed coordinate systems, as described in Sect. 7.3.4 of Paper I, may also be repaired. These are handled by cylfix().

Non-standard keywords:

The AIPS-convention CROTAn keywords are recognized as quasi-standard and as such are accommodated by wcsprm::crota[] and translated to wcsprm::pc[][] by wcsset(). These are not dealt with here, nor are any other non-standard keywords since these routines work only on the contents of a wcsprm struct and do not deal with FITS headers per se. In particular, they do not identify or translate CD00i00j, PC00i00j, PROJPn, EPOCH, VELREF or VSOURCEa keywords; this may be done by the FITS WCS header parser supplied with WCSLIB, refer to wcshdr.h.

wcsfix() and wcsfixi() apply all of the corrections handled by the following specific functions, which may also be invoked separately:

- cdfix(): Sets the diagonal element of the CDi_ja matrix to 1.0 if all CDi_ja keywords associated with a particular axis are omitted.
- datfix(): recast an older DATE-OBS date format in dateobs to year-2000 standard form. Derive dateref from
 mjdref if not already set. Alternatively, if dateref is set and mjdref isn't, then derive mjdref from it. If both are
 set, then check consistency. Likewise for dateobs and mjdobs; datebeg and mjdbeg; dateavg and mjdavg;
 and dateend and mjdend.
- obsfix(): if only one half of obsgeo[] is set, then derive the other half from it. If both halves are set, then check consistency.
- unitfix(): translate some commonly used but non-standard unit strings in the CUNITia keyvalues, e.g. 'DEG'
 'deg'.
- spcfix(): translate AIPS-convention spectral types, 'FREQ-LSR', 'FELO-HEL', etc., in ctype[] as set from CTYPEia.
- celfix(): translate AIPS-convention celestial projection types, NCP and GLS, in ctype[] as set from CTYPEia.
- cylfix(): fixes WCS keyvalues for malformed cylindrical projections that suffer from the problem described in Sect. 7.3.4 of Paper I.

6.27.4 Function Documentation

wcsfix()

```
int wcsfix (
          int ctrl,
```

```
const int naxis[],
struct wcsprm * wcs,
int stat[] )
```

Translate a non-standard WCS struct.

wcsfix() is identical to wcsfixi(), but lacks the info argument.

wcsfixi()

Translate a non-standard WCS struct.

wcsfixi() applies all of the corrections handled separately by cdfix(), datfix(), obsfix(), unitfix(), spcfix(), celfix(), and cylfix().

Parameters

in	ctrl	Do potentially unsafe translations of non-standard unit strings as described in the usage notes to wcsutrn().
in	naxis	Image axis lengths. If this array pointer is set to zero then cylfix() will not be invoked.
in,out	wcs	Coordinate transformation parameters.
out	stat	Status returns from each of the functions. Use the preprocessor macros NWCSFIX to dimension this vector and CDFIX, DATFIX, OBSFIX, UNITFIX, SPCFIX, CELFIX, and CYLFIX to access its elements. A status value of -2 is set for functions that were not invoked.
out	info	Status messages from each of the functions. Use the preprocessor macros NWCSFIX to dimension this vector and CDFIX, DATFIX, OBSFIX, UNITFIX, SPCFIX, CELFIX, and CYLFIX to access its elements. Note that the memory allocated by wcsfixi() for the message in each wcserr struct (wcserr::msg, if non-zero) must be freed by the user. See wcsdealloc().

Returns

Status return value:

- 0: Success.
- 1: One or more of the translation functions returned an error.

cdfix()

```
int cdfix ( {\tt struct\ wcsprm\ *\ wcs\ )}
```

Fix erroneously omitted CDi_ja keywords.

 $\mathbf{cdfix}()$ sets the diagonal element of the $\mathbf{CDi}_{_ja}$ matrix to unity if all $\mathbf{CDi}_{_ja}$ keywords associated with a given axis were omitted. According to WCS Paper I, if any $\mathbf{CDi}_{_ja}$ keywords at all are given in a FITS header then those not given default to zero. This results in a singular matrix with an intersecting row and column of zeros.

cdfix() is expected to be invoked before wcsset(), which will fail if these errors have not been corrected.

Parameters

rdinate transformation parameters.

Returns

Status return value:

- -1: No change required (not an error).
- 0: Success.
- 1: Null wcsprm pointer passed.

datfix()

Translate DATE-OBS and derive MJD-OBS or vice versa.

datfix() translates the old **DATE-OBS** date format set in wcsprm::dateobs to year-2000 standard form (*yyyy-mm-dd***T***hh:mm:ss*). It derives wcsprm::dateref from wcsprm::mjdref if not already set. Alternatively, if dateref is set and mjdref isn't, then it derives mjdref from it. If both are set but disagree by more than 0.001 day (86.4 seconds) then an error status is returned. Likewise for wcsprm::dateobs and wcsprm::mjdobs; wcsprm::datebeg and wcsprm::mjdbeg; wcsprm::dateavg and wcsprm::mjdavg; and wcsprm::dateend and wcsprm::mjdend.

If neither dateobs nor mjdobs are set, but wcsprm::jepoch (primarily) or wcsprm::bepoch is, then both are derived from it. If jepoch and/or bepoch are set but disagree with dateobs or mjdobs by more than 0.000002 year (63.2 seconds), an informative message is produced.

The translations done by **datfix**() do not affect and are not affected by wcsset().

Parameters

in,out	wcs	Coordinate transformation parameters. wcsprm::dateref and/or wcsprm::mjdref may be
		changed. wcsprm::dateobs and/or wcsprm::mjdobs may be changed. wcsprm::datebeg
		and/or wcsprm::mjdbeg may be changed. wcsprm::dateavg and/or wcsprm::mjdavg may
		be changed. wcsprm::dateend and/or wcsprm::mjdend may be changed.

Returns

Status return value:

- -1: No change required (not an error).
- · 0: Success.
- · 1: Null wcsprm pointer passed.
- 5: Invalid parameter value.

For returns >= 0, a detailed message, whether informative or an error message, may be set in wcsprm::err if enabled, see wcserr_enable(), with wcsprm::err.status set to FIXERR_DATE_FIX.

Notes:

1. The MJD algorithms used by **datfix**() are from D.A. Hatcher, 1984, QJRAS, 25, 53-55, as modified by P.T. Wallace for use in SLALIB subroutines *CLDJ* and *DJCL*.

obsfix()

complete the OBSGEO-[XYZLBH] vector of observatory coordinates.

obsfix() completes the wcsprm::obsgeo vector of observatory coordinates. That is, if only the (x,y,z) Cartesian coordinate triplet or the (I,b,h) geodetic coordinate triplet are set, then it derives the other triplet from it. If both triplets are set, then it checks for consistency at the level of 1 metre.

The operations done by **obsfix**() do not affect and are not affected by wcsset().

Parameters

in	ctrl	Flag that controls behaviour if one triplet is defined and the other is only partially defined:
		0: Reset only the undefined elements of an incomplete coordinate triplet.
		1: Reset all elements of an incomplete triplet.
		 2: Don't make any changes, check for consistency only. Returns an error if either of the two triplets is incomplete.
in,out	wcs	Coordinate transformation parameters. wcsprm::obsgeo may be changed.

Returns

Status return value:

- -1: No change required (not an error).
- · 0: Success.
- 1: Null wcsprm pointer passed.
- · 5: Invalid parameter value.

For returns >= 0, a detailed message, whether informative or an error message, may be set in wcsprm::err if enabled, see wcserr_enable(), with wcsprm::err.status set to FIXERR_OBS_FIX.

Notes:

- 1. While the International Terrestrial Reference System (ITRS) is based solely on Cartesian coordinates, it recommends the use of the GRS80 ellipsoid in converting to geodetic coordinates. However, while WCS Paper III recommends ITRS Cartesian coordinates, Paper VII prescribes the use of the IAU(1976) ellipsoid for geodetic coordinates, and consequently that is what is used here.
- 2. For reference, parameters of commonly used global reference ellipsoids:

```
a (m)
                1/f
                                        Standard
6378140
          298.2577
                           IAU(1976)
6378137
           298.257222101
                           GRS80
6378137
           298.257223563
6378136
                           IERS(1989)
           298.257
                           IERS(2003,2010), IAU(2009/2012)
6378136.6 298.25642
```

where f = (a - b) / a is the flattening, and a and b are the semi-major and semi-minor radii in metres.

3. The transformation from geodetic (lng,lat,hgt) to Cartesian (x,y,z) is

```
x = (n + hgt)*coslng*coslat,

y = (n + hgt)*sinlng*coslat,

z = (n*(1.0 - e^2) + hgt)*sinlat,
```

where the "prime vertical radius", n, is a function of latitude

```
n = a / sqrt(1 - (e*sinlat)^2),
```

and a, the equatorial radius, and $e^2 = (2 - f) * f$, the (first) eccentricity of the ellipsoid, are constants. **obsfix**() inverts these iteratively by writing

and iterating over the value of zeta. Since e is small, a good first approximation is given by zeta = z.

unitfix()

Correct aberrant CUNITia keyvalues.

unitfix() applies wcsutrn() to translate non-standard CUNITia keyvalues, e.g. 'DEG' -> 'deg', also stripping off unnecessary whitespace.

unitfix() is expected to be invoked before wcsset(), which will fail if non-standard CUNITia keyvalues have not been translated.

Parameters

in	ctrl	Do potentially unsafe translations described in the usage notes to wcsutrn().
in,out	wcs	Coordinate transformation parameters.

Returns

Status return value:

- -1: No change required (not an error).
- 0: Success (an alias was applied).
- · 1: Null wcsprm pointer passed.

When units are translated (i.e. 0 is returned), an informative message is set in wcsprm::err if enabled, see wcserr_enable(), with wcsprm::err.status set to FIXERR_UNITS_ALIAS.

spcfix()

```
int spcfix (
          struct wcsprm * wcs )
```

Translate AIPS-convention spectral types.

spcfix() translates AIPS-convention spectral coordinate types, '{FREQ,FELO,VELO}-{LSR,HEL,OBS}' (e.g. 'FREQ-OBS', 'FELO-HEL', 'VELO-LSR') set in wcsprm::ctype[], subject to VELREF set in wcsprm::velref.

Note that if wcs::specsys is already set then it will not be overridden.

AIPS-convention spectral types set in CTYPEia are translated on-the-fly by wcsset() but without modifying wcsprm::ctype[] or wcsprm::specsys. That is, only the information extracted from wcsprm::ctype[] is translated when wcsset() fills in wcsprm::spc (spcprm struct). spcfix() modifies wcsprm::ctype[] so that if the header is subsequently written out, e.g. by wcshdo(), then it will contain translated CTYPEia keyvalues.

The operations done by **spcfix**() do not affect and are not affected by wcsset().

Parameters

in,out	wcs	Coordinate transformation parameters. wcsprm::ctype[] and/or wcsprm::specsys may be	
		changed.	

Returns

Status return value:

- -1: No change required (not an error).
- · 0: Success.
- 1: Null wcsprm pointer passed.
- · 2: Memory allocation failed.
- 3: Linear transformation matrix is singular.
- 4: Inconsistent or unrecognized coordinate axis types.
- 5: Invalid parameter value.
- 6: Invalid coordinate transformation parameters.
- 7: Ill-conditioned coordinate transformation parameters.

For returns >= 0, a detailed message, whether informative or an error message, may be set in wcsprm::err if enabled, see wcserr_enable(), with wcsprm::err.status set to FIXERR_SPC_UPDTE.

celfix()

```
int celfix ( {\tt struct\ wcsprm\ *\ wcs\ )}
```

Translate AIPS-convention celestial projection types.

celfix() translates AIPS-convention celestial projection types, **NCP** and **GLS**, set in the ctype[] member of the wc-sprm struct.

Two additional pv[] keyvalues are created when translating **NCP**, and three are created when translating **GLS** with non-zero reference point. If the pv[] array was initially allocated by wcsini() then the array will be expanded if necessary. Otherwise, error 2 will be returned if sufficient empty slots are not already available for use.

AIPS-convention celestial projection types set in CTYPEia are translated on-the-fly by wcsset() but without modifying wcsprm::ctype[], wcsprm::pv[], or wcsprm::npv. That is, only the information extracted from wcsprm::ctype[] is translated when wcsset() fills in wcsprm::cel (celprm struct). celfix() modifies wcsprm::ctype[], wcsprm::pv[], and wcsprm::npv so that if the header is subsequently written out, e.g. by wcshdo(), then it will contain translated CTYPEia keyvalues and the relevant PVi_ma.

The operations done by **celfix**() do not affect and are not affected by wcsset(). However, it uses information in the wcsprm struct provided by wcsset(), and will invoke it if necessary.

Parameters

in,ou	wcs	Coordinate transformation parameters. wcsprm::ctype[] and/or wcsprm::pv[] may be changed.
-------	-----	---

Returns

Status return value:

- -1: No change required (not an error).
- 0: Success.
- 1: Null wcsprm pointer passed.
- 2: Memory allocation failed.
- 3: Linear transformation matrix is singular.
- · 4: Inconsistent or unrecognized coordinate axis types.
- 5: Invalid parameter value.
- 6: Invalid coordinate transformation parameters.
- 7: Ill-conditioned coordinate transformation parameters.

For returns > 1, a detailed error message is set in wcsprm::err if enabled, see wcserr_enable().

cylfix()

Fix malformed cylindrical projections.

cylfix() fixes WCS keyvalues for malformed cylindrical projections that suffer from the problem described in Sect. 7.3.4 of Paper I.

cylfix() requires the wcsprm struct to have been set up by wcsset(), and will invoke it if necessary. After modification, the struct is reset on return with an explicit call to wcsset().

Parameters

in	naxis	Image axis lengths.
in,out	wcs	Coordinate transformation parameters.

Returns

Status return value:

- -1: No change required (not an error).
- 0: Success.
- 1: Null wcsprm pointer passed.
- 2: Memory allocation failed.
- 3: Linear transformation matrix is singular.
- 4: Inconsistent or unrecognized coordinate axis types.

- 5: Invalid parameter value.
- 6: Invalid coordinate transformation parameters.
- 7: Ill-conditioned coordinate transformation parameters.
- 8: All of the corner pixel coordinates are invalid.
- 9: Could not determine reference pixel coordinate.
- 10: Could not determine reference pixel value.

For returns > 1, a detailed error message is set in wcsprm::err if enabled, see wcserr_enable().

wcspcx()

regularize PCi_j.

wcspcx() "regularizes" the linear transformation matrix component of the coordinate transformation (PCi_ja) to make it more human-readable.

Normally, upon encountering a FITS header containing a CDi_ja matrix, wcsset() simply treats it as PCi_ja and sets CDELTia to unity. However, wcspcx() decomposes CDi_ja into PCi_ja and CDELTia in such a way that CDELTia form meaningful scaling parameters. In practice, the residual PCi_ja matrix will often then be orthogonal, i.e. unity, or describing a pure rotation, axis permutation, or reflection, or a combination thereof.

The decomposition is based on normalizing the length in the transformed system (i.e. intermediate pixel coordinates) of the orthonormal basis vectors of the pixel coordinate system. This deviates slightly from the prescription given by Eq. (4) of WCS Paper I, namely $Sum(j=1,N)(\mathbf{PC}_{j=1})^2 = 1$, in replacing the sum over j with the sum over i. Consequently, the columns of $\mathbf{PC}_{j=1}$ will consist of unit vectors. In practice, especially in cubes and higher dimensional images, at least some pairs of these unit vectors, if not all, will often be orthogonal or close to orthogonal.

The sign of **CDELT**ia is chosen to make the **PC**i_ja matrix as close to the, possibly permuted, unit matrix as possible, except that where the coordinate description contains a pair of celestial axes, the sign of **CDELT**ia is set negative for the longitude axis and positive for the latitude axis.

Optionally, rows of the **PC**i_ja matrix may also be permuted to diagonalize it as far as possible, thus undoing any transposition of axes in the intermediate pixel coordinate system.

If the coordinate description contains a celestial plane, then the angle of rotation of each of the basis vectors associated with the celestial axes is returned. For a pure rotation the two angles should be identical. Any difference between them is a measure of axis skewness.

The decomposition is not performed for axes involving a sequent distortion function that is defined in terms of $\mathtt{CDi_ja}$, such as TPV, TNX, or ZPX, which always are. The independent variables of the polynomial are therefore intermediate world coordinates rather than intermediate pixel coordinates. Because sequent distortions are always applied before $\mathtt{CDELTia}$, if $\mathtt{CDi_ja}$ was translated to $\mathtt{PCi_ja}$ plus $\mathtt{CDELTia}$, then the distortion would be altered unless the polynomial coefficients were also adjusted to account for the change of scale.

wcspcx() requires the wcsprm struct to have been set up by wcsset(), and will invoke it if necessary. The wcsprm struct is reset on return with an explicit call to wcsset().

Parameters

in,out	wcs	Coordinate transformation parameters.
in	dopc	If 1, then PCi_ja and CDELTia, as given, will be recomposed according to the above prescription. If 0, the operation is restricted to decomposing CDi_ja.
in	permute	If 1, then after decomposition (or recomposition), permute rows of PCi_ja to make the axes of the intermediate pixel coordinate system match as closely as possible those of the pixel coordinates. That is, make it as close to a diagonal matrix as possible. However, celestial axes are special in always being paired, with the longitude axis preceding the latitude axis. All WCS entities indexed by i, such as CTYPEia, CRVALia, CDELTia, etc., including coordinate lookup tables, will also be permuted as necessary to account for the change to PCi_ja. This does not apply to CRPIXja, nor prior distortion functions. These operate on pixel coordinates, which are not affected by the permutation.
out	rotn	with the celestial axes. For a pure rotation the two angles should be identical. Any difference between them is a measure of axis skewness. May be set to the NULL pointer if this information is not required.

Returns

Status return value:

- 0: Success.
- 1: Null wcsprm pointer passed.
- · 2: Memory allocation failed.
- 5: CDi_j matrix not used.
- 6: Sequent distortion function present.

00050 *
00051 \star Repairs effected by these routines range from the translation of
00052 \star non-standard values for standard WCS keywords, to the repair of malformed
00053 \, \star \, \text{coordinate} representations. Some routines are also provided to check the
00054 \star consistency of pairs of keyvalues that define the same measure in two
00055 \star different ways, for example, as a date and an MJD.
00056 *
00057 \star A separate routine, wcspcx(), "regularizes" the linear transformation matrix
00058 * component (PCi_j) of the coordinate transformation to make it more human-
        readable. Where a coordinate description was constructed from CDi_j, it
00060 \star decomposes it into PCi_j + CDELTi in a meaningful way. Optionally, it can
00061 \star also diagonalize the PCi_j matrix (as far as possible), i.e. undo a
00062 \star transposition of axes in the intermediate pixel coordinate system.
00063 *
00064 * Non-standard kevvalues:
00065 *
00066 *
          AIPS-convention celestial projection types, NCP and GLS, and spectral
00067 *
          types, 'FREQ-LSR', 'FELO-HEL', etc., set in CTYPEia are translated
00068 *
          on-the-fly by wcsset() but without modifying the relevant ctype[], pv[] or
00069 *
          specsys members of the wcsprm struct. That is, only the information
          extracted from ctype[] is translated when wcsset() fills in wcsprm::cel
00070 *
00071 *
          (celprm struct) or wcsprm::spc (spcprm struct).
00072 *
00073 *
          On the other hand, these routines do change the values of wcsprm::ctype[],
00074 *
          wcsprm::pv[], wcsprm::specsys and other wcsprm struct members as
00075 *
          appropriate to produce the same result as if the FITS header itself had
00076 *
          been translated.
00077 *
00078 *
          Auxiliary WCS header information not used directly by WCSLIB may also be
00079 *
          translated. For example, the older DATE-OBS date format (wcsprm::dateobs)
00080 *
          is recast to year-2000 standard form, and MJD-OBS (wcsprm::mjdobs) will be
00081 *
          deduced from it if not already set.
00082 *
00083 *
          Certain combinations of keyvalues that result in malformed coordinate
00084 *
          systems, as described in Sect. 7.3.4 of Paper I, may also be repaired.
00085 *
          These are handled by cylfix().
00086 *
00087 * Non-standard keywords:
00088 * --
00089 *
          The AIPS-convention CROTAn keywords are recognized as quasi-standard
00090
          and as such are accomodated by wcsprm::crota[] and translated to
          wcsprm::pc[][] by wcsset(). These are not dealt with here, nor are any
00091 *
00092 *
          other non-standard keywords since these routines work only on the contents
                                                                            T.n
00093 *
          of a wcsprm struct and do not deal with FITS headers per se.
          particular, they do not identify or translate CD00i00j, PC00i00j, PROJPn, EPOCH, VELREF or VSOURCEa keywords; this may be done by the FITS WCS
00094 *
00095 *
          header parser supplied with WCSLIB, refer to wcshdr.h.
00097 *
00098 \star wcsfix() and wcsfixi() apply all of the corrections handled by the following
00099 \star specific functions, which may also be invoked separately:
00100 *
00101 *
          - cdfix(): Sets the diagonal element of the CDi ja matrix to 1.0 if all
```

```
CDi_ja keywords associated with a particular axis are omitted.
00103 *
00104 *
          - datfix(): recast an older DATE-OBS date format in dateobs to year-2000
00105 *
            standard form. Derive dateref from mjdref if not already set.
            Alternatively, if dateref is set and mjdref isn't, then derive mjdref
00106 *
            from it. If both are set, then check consistency. Likewise for dateobs
00107 *
            and mjdobs; datebeg and mjdbeg; dateavg and mjdavg; and dateend and
00109 *
00110 *
00111 *
          - obsfix(): if only one half of obsgeo[] is set, then derive the other
           half from it. If both halves are set, then check consistency.
00112 *
00113 *
          - unitfix(): translate some commonly used but non-standard unit strings in the CUNITia keyvalues, e.g. 'DEG' -> 'deg'.
00114 *
00115 *
00116 *
          - spcfix(): translate AIPS-convention spectral types, 'FREQ-LSR',
    'FELO-HEL', etc., in ctype[] as set from CTYPEia.
00117 *
00118 *
00119 *
          - celfix(): translate AIPS-convention celestial projection types, NCP and
00121 *
           GLS, in ctype[] as set from CTYPEia.
00122 *
00123 *
          - cylfix(): fixes WCS keyvalues for malformed cylindrical projections that
          suffer from the problem described in Sect. 7.3.4 of Paper I.
00124 *
00125 *
00126 *
00127 * wcsfix() - Translate a non-standard WCS struct
00128 *
00129 \star wcsfix() is identical to wcsfixi(), but lacks the info argument.
00130 *
00131 +
00132 * wcsfixi() - Translate a non-standard WCS struct
00133 *
00134 \star wcsfixi() applies all of the corrections handled separately by cdfix(),
00135 * datfix(), obsfix(), unitfix(), spcfix(), celfix(), and cylfix().
00136 *
00137 * Given:
00138 *
                               Do potentially unsafe translations of non-standard
         ctrl
                    int
00139 *
                               unit strings as described in the usage notes to
00140 *
                               wcsutrn().
00141 *
00142 *
         naxis
                    const int []
                               Image axis lengths. If this array pointer is set to zero then cylfix() will not be invoked.
00143 *
00144 *
00145 *
00146 * Given and returned:
00147 *
         WCS
                    struct wcsprm*
00148 *
                               Coordinate transformation parameters.
00149 *
00150 * Returned:
00151 *
                    int [NWCSFIX]
         stat
00152 +
                               Status returns from each of the functions. Use the
                               preprocessor macros NWCSFIX to dimension this vector
00153 *
00154 *
                                and CDFIX, DATFIX, OBSFIX, UNITFIX, SPCFIX, CELFIX,
00155 *
                               and CYLFIX to access its elements. A status value
00156 *
                               of -2 is set for functions that were not invoked.
00157 *
                    struct wcserr [NWCSFIX]
          info
00159 *
                               Status messages from each of the functions. Use the
00160 *
                               preprocessor macros NWCSFIX to dimension this vector
00161 *
                                and CDFIX, DATFIX, OBSFIX, UNITFIX, SPCFIX, CELFIX,
00162 *
                               and CYLFIX to access its elements.
00163 *
00164 *
                               Note that the memory allocated by wcsfixi() for the
                               message in each wcserr struct (wcserr::msg, if
00165 *
00166 *
                               non-zero) must be freed by the user.
                               wcsdealloc().
00167 *
00168 *
00169 * Function return value:
00170 *
                               Status return value:
                    int
00171 *
                                 0: Success.
00172 *
                                 1: One or more of the translation functions
00173 *
                                     returned an error.
00174 *
00175 *
00176 * cdfix() - Fix erroneously omitted CDi_ja keywords
00178 \star cdfix() sets the diagonal element of the CDi_ja matrix to unity if all
00179 \star CDi_ja keywords associated with a given axis were omitted. According to WCS
00180 \star Paper I, if any CDi_ja keywords at all are given in a FITS header then those
00181 \star \text{not given default to zero.} This results in a singular matrix with an
00182 * intersecting row and column of zeros.
00184 * cdfix() is expected to be invoked before wcsset(), which will fail if these
00185 * errors have not been corrected.
00186 *
00187 \star Given and returned:
00188 *
         WCS
                    struct wcsprm*
```

```
00189 *
                               Coordinate transformation parameters.
00190 *
00191 * Function return value:
00192 *
                    int
                                Status return value:
00193 *
                                 -1: No change required (not an error).
00194 *
                                  0: Success.
00195 *
                                  1: Null wcsprm pointer passed.
00196 *
00197
00198 * datfix() - Translate DATE-OBS and derive MJD-OBS or vice versa
00199 *
00200 \star datfix() translates the old DATE-OBS date format set in wcsprm::dateobs to
00201 * year-2000 standard form (yyyy-mm-ddThh:mm:ss). It derives wcsprm::dateref 00202 * from wcsprm::mjdref if not already set. Alternatively, if dateref is set
00203 \star and mjdref isn't, then it derives mjdref from it. If both are set but
00204 \star disagree by more than 0.001 day (86.4 seconds) then an error status is
00205 * returned. Likewise for wcsprm::dateobs and wcsprm::mjdobs; wcsprm::datebeg
00206 \star and wcsprm::mjdbeg; wcsprm::dateavg and wcsprm::mjdavg; and wcsprm::dateend
00207 * and wcsprm::mjdend.
00208
00209 \star If neither dateobs nor mjdobs are set, but wcsprm::jepoch (primarily) or
00210 \star wcsprm::bepoch is, then both are derived from it. If jepoch and/or bepoch
00211 \star are set but disagree with dateobs or mjdobs by more than 0.000002 year
00212 * (63.2 seconds), an informative message is produced.
00213 *
00214 \star The translations done by datfix() do not affect and are not affected by
00215 * wcsset().
00216 *
00217 * Given and returned:
00218 *
          WCS
                    struct wcsprm*
00219 *
                                Coordinate transformation parameters.
00220 *
                                wcsprm::dateref and/or wcsprm::mjdref may be changed.
00221 *
                                wcsprm::dateobs and/or wcsprm::mjdobs may be changed.
00222 *
                                wcsprm::datebeg and/or wcsprm::mjdbeg may be changed.
00223 *
                                wcsprm::dateavg and/or wcsprm::mjdavg may be changed.
00224 *
                                wcsprm::dateend and/or wcsprm::mjdend may be changed.
00225 *
00226 * Function return value:
00227 *
                                Status return value:
00228 *
                                 -1: No change required (not an error).
00229 *
                                  0: Success.
00230 *
                                  1: Null wcsprm pointer passed.
00231 *
                                  5: Invalid parameter value.
00232 *
00233
                                For returns >= 0, a detailed message, whether
00234 *
                                informative or an error message, may be set in
00235 *
                                wcsprm::err if enabled, see wcserr_enable(), with
00236 *
                                wcsprm::err.status set to FIXERR_DATE_FIX.
00237 *
00238 * Notes:
         1: The MJD algorithms used by datfix() are from D.A. Hatcher, 1984, QJRAS,
              25, 53-55, as modified by P.T. Wallace for use in SLALIB subroutines
00240 *
00241 *
             CLDJ and DJCL.
00242 *
00243 *
00244 \star obsfix() - complete the OBSGEO-[XYZLBH] vector of observatory coordinates
00246 \star obsfix() completes the wcsprm::obsgeo vector of observatory coordinates.
00247 \star That is, if only the (x,y,z) Cartesian coordinate triplet or the (1,b,h)
00248 \star geodetic coordinate triplet are set, then it derives the other triplet from
00249 \star it. If both triplets are set, then it checks for consistency at the level
00250 * of 1 metre.
00251 *
00252 \star The operations done by obsfix() do not affect and are not affected by
00253 * wcsset().
00254 *
00255 * Given:
00256 *
                                Flag that controls behaviour if one triplet is
          ctrl
                     int
00257 *
                                defined and the other is only partially defined:
00258 *
                                  0: Reset only the undefined elements of an
00259 *
                                     incomplete coordinate triplet.
00260 *
                                  1: Reset all elements of an incomplete triplet.
                                  2: Don't make any changes, check for consistency only. Returns an error if either of the two
00261 *
00262 *
00263 *
                                     triplets is incomplete.
00264 *
00265 * Given and returned:
00266 * wcs struct wcsprm*
00267 *
                                Coordinate transformation parameters.
00268 *
                                wcsprm::obsgeo may be changed.
00269 *
00270 * Function return value:
00271 *
                    int
                                Status return value:
00272 *
                                 -1: No change required (not an error).
00273 *
                                  0: Success.
00274 *
                                  1: Null wcsprm pointer passed.
00275 *
                                  5: Invalid parameter value.
```

```
For returns >= 0, a detailed message, whether
00277 *
00278 *
                                informative or an error message, may be set in
                                wcsprm::err if enabled, see wcserr_enable(), with
00279 *
00280 *
                                wcsprm::err.status set to FIXERR_OBS_FIX.
00281 *
00283 *
          1: While the International Terrestrial Reference System (ITRS) is based
00284 *
              solely on Cartesian coordinates, it recommends the use of the {\tt GRS80}
             ellipsoid in converting to geodetic coordinates. However, while WCS Paper III recommends ITRS Cartesian coordinates, Paper VII prescribes
00285 *
00286 *
             the use of the IAU(1976) ellipsoid for geodetic coordinates, and
00287 *
00288 *
             consequently that is what is used here.
00289 *
00290 *
          2: For reference, parameters of commonly used global reference ellipsoids:
00291 *
00292 =
                 a (m)
                                  1/f
                                                           Standard
00293 =
               6378140 298.2577
                                           IAU(1976)
00295 =
                           298.257222101
                6378137
                           298.257223563 WGS84
00296 =
                6378137
00297 =
                6378136
                           298.257
                                             IERS (1989)
00298 =
               6378136.6 298.25642
                                            IERS(2003,2010), IAU(2009/2012)
00299 *
00300 *
              where f = (a - b) / a is the flattening, and a and b are the semi-major
             and semi-minor radii in metres.
00301 *
00302 *
00303 *
          3: The transformation from geodetic (lng, lat, hgt) to Cartesian (x, y, z) is
00304 *
00305 =
                x = (n + hgt) * coslng * coslat,
                y = (n + hgt)*sinlng*coslat,

z = (n*(1.0 - e^2) + hgt)*sinlat,
00306 =
00307 =
00308 *
00309 *
              where the "prime vertical radius", n, is a function of latitude
00310 *
                n = a / sqrt(1 - (e*sinlat)^2),
00311 =
00312 *
             and a, the equatorial radius, and e^2 = (2 - f) *f, the (first)
00314 *
              eccentricity of the ellipsoid, are constants. obsfix() inverts these
00315 *
              iteratively by writing
00316 *
00317 =
                   x = rho * coslng * coslat,
00318 =
                   v = rho*sinlng*coslat.
               zeta = rho*sinlat,
00319 =
00320 *
00321 *
              where
00322 *
                rho = n + hgt,
= sqrt(x^2 + y^2 + zeta^2),
00323 =
00324 =
               zeta = z / (1 - n*e^2/rho),
00325 =
00326 *
00327 *
              and iterating over the value of zeta. Since e is small, a good first
00328 *
              approximation is given by zeta = z.
00329 *
00330 *
00331 * unitfix() - Correct aberrant CUNITia keyvalues
00333 * unitfix() applies wcsutrn() to translate non-standard CUNITia keyvalues,
00334 * e.g. 'DEG' -> 'deg', also stripping off unnecessary whitespace.
00335 *
00336 \star unitfix() is expected to be invoked before wcsset(), which will fail if
00337 \star non-standard CUNITia keyvalues have not been translated.
00338 *
00339 * Given:
00340 * ctrl
                               Do potentially unsafe translations described in the
00341 *
                                usage notes to wcsutrn().
00342 *
00343 * Given and returned:
00344 * wcs
                    struct wcsprm*
00345 *
                                Coordinate transformation parameters.
00346 *
00347 * Function return value:
00348 *
                     int
                                Status return value:
00349 *
                                 -1: No change required (not an error).
00350 *
                                  0: Success (an alias was applied).
00351 *
                                  1: Null wcsprm pointer passed.
00352 *
00353 *
                                When units are translated (i.e. 0 is returned), an
00354 *
                                informative message is set in wcsprm::err if enabled,
00355 *
                                see wcserr_enable(), with wcsprm::err.status set to
00356 *
                                FIXERR UNITS ALIAS.
00357
00358 *
00359 * spcfix() - Translate AIPS-convention spectral types
00360 * ---
00361 * spcfix() translates AIPS-convention spectral coordinate types, 00362 * '{FREQ.FELO.VELO}-{LSR,HEL,OBS}' (e.g. 'FREQ-OBS', 'FELO-HEL', 'VELO-LSR')
```

```
00363 * set in wcsprm::ctype[], subject to VELREF set in wcsprm::velref.
00365 \star Note that if wcs::specsys is already set then it will not be overridden.
00366 *
00367 \star AIPS-convention spectral types set in CTYPEia are translated on-the-fly by
00368 * wcsset() but without modifying wcsprm::ctype[] or wcsprm::specsys.
                                                                                That is,
00369 * only the information extracted from wcsprm::ctype[] is translated when
00370 \star wcsset() fills in wcsprm::spc (spcprm struct). spcfix() modifies
00371 \star wcsprm::ctype[] so that if the header is subsequently written out, e.g. by
00372 \star wcshdo(), then it will contain translated CTYPEia keyvalues.
00373 *
00374 \star The operations done by spcfix() do not affect and are not affected by
00375 * wcsset().
00376 *
00377 * Given and returned:
00378 *
         WCS
                   struct wcsprm*
00379 *
                                Coordinate transformation parameters. wcsprm::ctype[]
00380 *
                               and/or wcsprm::specsys may be changed.
00381 *
00382 * Function return value:
00383 *
                               Status return value:
00384 *
                                 -1: No change required (not an error).
00385 *
                                  0: Success.
00386 *
                                  1: Null wcsprm pointer passed.
00387 *
                                  2: Memory allocation failed.
                                  3: Linear transformation matrix is singular.
00388 *
00389 *
                                  4: Inconsistent or unrecognized coordinate axis
00390 *
00391 *
                                  5: Invalid parameter value.
00392 *
                                  6: Invalid coordinate transformation parameters.
00393 *
                                  7: Ill-conditioned coordinate transformation
00394 *
                                     parameters.
00395 *
00396 *
                                For returns >= 0, a detailed message, whether
                                informative or an error message, may be set in
wcsprm::err if enabled, see wcserr_enable(), with
00397 *
00398 *
00399 *
                                wcsprm::err.status set to FIXERR_SPC_UPDTE.
00401
00402 * celfix() - Translate AIPS-convention celestial projection types
00403 *
00404 * celfix() translates AIPS-convention celestial projection types, NCP and
00405 * GLS, set in the ctype[] member of the wcsprm struct.
00406
00407 \star Two additional pv[] keyvalues are created when translating NCP, and three
00408 \star are created when translating GLS with non-zero reference point. If the pv[]
00409 \star array was initially allocated by wcsini() then the array will be expanded if
00410 \star necessary. Otherwise, error 2 will be returned if sufficient empty slots
00411 \star are not already available for use.
00412 *
00413 \star AIPS-convention celestial projection types set in CTYPEia are translated
00414 * on-the-fly by wcsset() but without modifying wcsprm::ctype[], wcsprm::pv[],
00415 \star or wcsprm::npv. That is, only the information extracted from
00416 * wcsprm::ctype[] is translated when wcsset() fills in wcsprm::cel (celprm
00417 \star struct). celfix() modifies wcsprm::ctype[], wcsprm::pv[], and wcsprm::npv
00418 * so that if the header is subsequently written out, e.g. by wcshdo(), then it 00419 * will contain translated CTYPEia keyvalues and the relevant PVi_ma.
00420 *
00421 \star The operations done by celfix() do not affect and are not affected by
00422 \star wcsset(). However, it uses information in the wcsprm struct provided by
00423 * wcsset(), and will invoke it if necessary.
00424 *
00425 * Given and returned:
00426 * wcs
                   struct wcsprm*
00427 *
                                Coordinate transformation parameters. wcsprm::ctype[]
00428 *
                                and/or wcsprm::pv[] may be changed.
00429 *
00430 * Function return value:
00431 *
                               Status return value:
                    int
00432 *
                                 -1: No change required (not an error).
00433 *
                                  0: Success.
00434 *
                                  1: Null wcsprm pointer passed.
00435 *
                                  2: Memory allocation failed.
00436 *
                                  3: Linear transformation matrix is singular.
00437 *
                                  4: Inconsistent or unrecognized coordinate axis
00438
                                     types.
00439 *
                                  5: Invalid parameter value.
00440 *
                                  6: Invalid coordinate transformation parameters.
00441 *
                                  7: Ill-conditioned coordinate transformation
00442 *
                                     parameters.
00443 *
00444
                                For returns > 1, a detailed error message is set in
                                wcsprm::err if enabled, see wcserr_enable().
00445 *
00446 *
00447
00448 * cylfix() - Fix malformed cylindrical projections
00449 *
```

```
00450 \star cylfix() fixes WCS keyvalues for malformed cylindrical projections that
00451 * suffer from the problem described in Sect. 7.3.4 of Paper I.
00452 *
00453 \star cylfix() requires the wcsprm struct to have been set up by wcsset(), and
00454 \star will invoke it if necessary. After modification, the struct is reset on 00455 \star return with an explicit call to wcsset().
00457 * Given:
00458 * naxis
                      const int []
00459 *
                                 Image axis lengths.
00460 *
00461 * Given and returned:
00462 *
          WCS
                    struct wcsprm*
00463 *
                                 Coordinate transformation parameters.
00464 *
00465 * Function return value:
00466 *
                      int
                                 Status return value:
00467 *
                                  -1: No change required (not an error).
                                   0: Success.
00469 *
                                   1: Null wcsprm pointer passed.
                                   2: Memory allocation failed.
00470 *
00471 *
                                   3: Linear transformation matrix is singular.
00472 *
                                   4: Inconsistent or unrecognized coordinate axis
00473 *
                                       types.
00474 *
                                   5: Invalid parameter value.
                                   6: Invalid coordinate transformation parameters.
00475 *
00476 *
                                   7: Ill-conditioned coordinate transformation
00477 *
                                       parameters.
00478 *
                                   8: All of the corner pixel coordinates are invalid.
00479 *
                                   9\colon \mbox{Could} not determine reference pixel coordinate.
00480
                                  10: Could not determine reference pixel value.
00481 *
00482 *
                                 For returns > 1, a detailed error message is set in
00483 *
                                 wcsprm::err if enabled, see wcserr_enable().
00484 *
00485 *
00486 * wcspcx() - regularize PCi j
00488 \star wcspcx() "regularizes" the linear transformation matrix component of the
00489 * coordinate transformation (PCi_ja) to make it more human-readable.
00490 *
00491 * Normally, upon encountering a FITS header containing a CDi ja matrix,
00492 \star wcsset() simply treats it as PCi_ja and sets CDELTia to unity. However,
00493 * wcspcx() decomposes CDi_ja into PCi_ja and CDELTia in such a way that
00494 * CDELTia form meaningful scaling parameters. In practice, the residual 00495 * PCi_ja matrix will often then be orthogonal, i.e. unity, or describing a
00496 \star pure rotation, axis permutation, or reflection, or a combination thereof.
00497 *
00498 \star \text{The decomposition} is based on normalizing the length in the transformed
00499 \star system (i.e. intermediate pixel coordinates) of the orthonormal basis
00500 * vectors of the pixel coordinate system. This deviates slightly from the 00501 * prescription given by Eq. (4) of WCS Paper I, namely Sum(j=1,N)(PCi_ja)<sup>2</sup> = 1,
00502 \star in replacing the sum over j with the sum over i. Consequently, the columns
00503 \star of PCi_ja will consist of unit vectors. In practice, especially in cubes 00504 \star and higher dimensional images, at least some pairs of these unit vectors, if
00505 * not all, will often be orthogonal or close to orthogonal.
00507 \star The sign of CDELTia is chosen to make the PCi_ja matrix as close to the,
00508 \star possibly permuted, unit matrix as possible, except that where the coordinate
00509 \star description contains a pair of celestial axes, the sign of CDELTia is set
00510 \star negative for the longitude axis and positive for the latitude axis.
00511 *
00512 \star Optionally, rows of the PCi_ja matrix may also be permuted to diagonalize
00513 \star it as far as possible, thus undoing any transposition of axes in the
00514 * intermediate pixel coordinate system.
00515 *
00516 \star If the coordinate description contains a celestial plane, then the angle of
00517 * rotation of each of the basis vectors associated with the celestial axes is
00518 \star returned. For a pure rotation the two angles should be identical. Any
00519 * difference between them is a measure of axis skewness.
00520 *
00521 \star The decomposition is not performed for axes involving a sequent distortion
00522 * function that is defined in terms of CDi_ja, such as TPV, TNX, or ZPX, which
00523 \star always are. The independent variables of the polynomial are therefore
00524 \, \star \, \text{intermediate world coordinates rather than intermediate pixel coordinates.}
00525 * Because sequent distortions are always applied before CDELTia, if CDi_ja was
00526 \star translated to PCi_ja plus CDELTia, then the distortion would be altered
00527 \star unless the polynomial coefficients were also adjusted to account for the
00528 * change of scale.
00529 *
00530 \star wcspcx() requires the wcsprm struct to have been set up by wcsset(), and
00531 \star will invoke it if necessary. The wcsprm struct is reset on return with an
00532 * explicit call to wcsset().
00533 *
00534 * Given and returned:
00535 * wcs
                      struct wcsprm*
00536 *
                                 Coordinate transformation parameters.
```

```
00537 *
00538 * Given:
00539 *
                    int
                               If 1, then PCi_ja and CDELTia, as given, will be
          dopc
                               recomposed according to the above prescription. If \mathbf{0},
00540 *
00541 *
                               the operation is restricted to decomposing CDi_ja.
00542 *
          permute
                   int
                               If 1, then after decomposition (or recomposition),
00544 *
                               permute rows of PCi_ja to make the axes of the
00545 *
                               intermediate pixel coordinate system match as closely
00546 *
                               as possible those of the pixel coordinates. That is,
00547 *
                               make it as close to a diagonal matrix as possible.
00548 *
                               However, celestial axes are special in always being
00549 *
                               paired, with the longitude axis preceding the latitude
00550 *
00551 *
00552 *
                               All WCS entities indexed by i, such as CTYPEia,
                               CRVALia, CDELTia, etc., including coordinate lookup
00553 *
                               tables, will also be permuted as necessary to account for the change to PCi_ja. This does not apply to CRPIXja, nor prior distortion functions. These
00554 *
00555
00556
00557 *
                               operate on pixel coordinates, which are not affected
00558 *
                               by the permutation.
00559 *
00560 * Returned:
00561 *

Enumerations

```
    enum wcshdr_errmsg_enum {
    WCSHDRERR_SUCCESS = 0 , WCSHDRERR_NULL_POINTER = 1 , WCSHDRERR_MEMORY = 2 , WCSHDRERR_BAD_COLUMN = 3 , WCSHDRERR_PARSER = 4 , WCSHDRERR_BAD_TABULAR_PARAMS = 5 }
```

Functions

- int wcspih (char *header, int nkeyrec, int relax, int ctrl, int *nreject, int *nwcs, struct wcsprm **wcs)

 FITS WCS parser routine for image headers.
- int wcsbth (char *header, int nkeyrec, int relax, int ctrl, int keysel, int *colsel, int *nreject, int *nwcs, struct wcsprm **wcs)

FITS WCS parser routine for binary table and image headers.

int wcstab (struct wcsprm *wcs)

Tabular construction routine.

int wcsidx (int nwcs, struct wcsprm **wcs, int alts[27])

Index alternate coordinate representations.

int wcsbdx (int nwcs, struct wcsprm **wcs, int type, short alts[1000][28])

Index alternate coordinate representions.

int wcsvfree (int *nwcs, struct wcsprm **wcs)

Free the array of wcsprm structs.

• int wcshdo (int ctrl, struct wcsprm *wcs, int *nkeyrec, char **header)

Write out a wcsprm struct as a FITS header.

Variables

• const char * wcshdr_errmsg[]

Status return messages.

6.29.1 Detailed Description

Routines in this suite are aimed at extracting WCS information from a FITS file. The information is encoded via keywords defined in

```
"Representations of world coordinates in FITS",
Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061 (WCS Paper I)

"Representations of celestial coordinates in FITS",
Calabretta, M.R., & Greisen, E.W. 2002, A&A, 395, 1077 (WCS Paper II)

"Representations of spectral coordinates in FITS",
Greisen, E.W., Calabretta, M.R., Valdes, F.G., & Allen, S.L.
2006, A&A, 446, 747 (WCS Paper III)

"Representations of distortions in FITS world coordinate systems",
Calabretta, M.R. et al. (WCS Paper IV, draft dated 2004/04/22),
available from http://www.atnf.csiro.au/people/Mark.Calabretta

"Representations of time coordinates in FITS -
Time and relative dimension in space",
Rots, A.H., Bunclark, P.S., Calabretta, M.R., Allen, S.L.,
Manchester, R.N., & Thompson, W.T. 2015, A&A, 574, A36 (WCS Paper VII)
```

These routines provide the high-level interface between the FITS file and the WCS coordinate transformation routines.

Additionally, function wcshdo() is provided to write out the contents of a wcsprm struct as a FITS header.

Briefly, the anticipated sequence of operations is as follows:

- 1: Open the FITS file and read the image or binary table header, e.g. using CFITSIO routine fits_hdr2str().
- 2: Parse the header using wcspih() or wcsbth(); they will automatically interpret 'TAB' header keywords using wcstab().
- 3: Allocate memory for, and read 'TAB' arrays from the binary table extension, e.g. using CFITSIO routine fits_read_wcstab() refer to the prologue of getwcstab.h. wcsset() will automatically take control of this allocated memory, in particular causing it to be freed by wcsfree().
- 4: Translate non-standard WCS usage using wcsfix(), see wcsfix.h.
- 5: Initialize wcsprm struct(s) using wcsset() and calculate coordinates using wcsp2s() and/or wcss2p(). Refer to the prologue of wcs.h for a description of these and other high-level WCS coordinate transformation routines.
- 6: Clean up by freeing memory with wcsvfree().

In detail:

- wcspih() is a high-level FITS WCS routine that parses an image header. It returns an array of up to 27 wcsprm structs on each of which it invokes wcstab().
- wcsbth() is the analogue of wcspih() for use with binary tables; it handles image array and pixel list keywords. As an extension of the FITS WCS standard, it also recognizes image header keywords which may be used to provide default values via an inheritance mechanism.
- wcstab() assists in filling in members of the wcsprm struct associated with coordinate lookup tables ('TAB').
 These are based on arrays stored in a FITS binary table extension (BINTABLE) that are located by PVi_ma keywords in the image header.
- wcsidx() and wcsbdx() are utility routines that return the index for a specified alternate coordinate descriptor in the array of wcsprm structs returned by wcspih() or wcsbth().
- wcsvfree() deallocates memory for an array of wcsprm structs, such as returned by wcspih() or wcsbth().
- wcshdo() writes out a wcsprm struct as a FITS header.

6.29.2 Macro Definition Documentation

WCSHDR none

```
#define WCSHDR_none 0x00000000
```

Bit mask for wcspih() and wcsbth() - reject all extensions.

Bit mask for the *relax* argument of wcspih() and wcsbth() - reject all extensions.

Refer to wcsbth() note 5.

WCSHDR_all

```
#define WCSHDR_all 0x000FFFFF
```

Bit mask for wcspih() and wcsbth() - accept all extensions.

Bit mask for the *relax* argument of wcspih() and wcsbth() - accept all extensions.

WCSHDR_reject

```
#define WCSHDR_reject 0x10000000
```

Bit mask for wcspih() and wcsbth() - reject non-standard keywords.

Bit mask for the relax argument of wcspih() and wcsbth() - reject non-standard keywords.

Refer to wcsbth() note 5.

WCSHDR_strict

```
#define WCSHDR_strict 0x20000000
```

WCSHDR_CROTAia

```
#define WCSHDR_CROTAia 0x0000001
```

Bit mask for wcspih() and wcsbth() - accept CROTAia, iCROTna, TCROTna.

Bit mask for the relax argument of wcspih() and wcsbth() - accept CROTAia, iCROTna, TCROTna.

Refer to wcsbth() note 5.

WCSHDR_VELREFa

```
#define WCSHDR_VELREFa 0x00000002
```

Bit mask for wcspih() and wcsbth() - accept VELREFa.

Bit mask for the relax argument of wcspih() and wcsbth() - accept VELREFa.

Refer to wcsbth() note 5.

WCSHDR_CD00i00j

```
#define WCSHDR_CD00i00j 0x00000004
```

Bit mask for wcspih() and wcsbth() - accept CD00i00j.

Bit mask for the *relax* argument of wcspih() and wcsbth() - accept CD00i00j.

Refer to wcsbth() note 5.

WCSHDR_PC00i00j

```
#define WCSHDR_PC00i00j 0x00000008
```

Bit mask for wcspih() and wcsbth() - accept PC00i00j.

Bit mask for the *relax* argument of wcspih() and wcsbth() - accept PC00i00j.

WCSHDR_PROJPn

#define WCSHDR_PROJPn 0x00000010

Bit mask for wcspih() and wcsbth() - accept PROJPn.

Bit mask for the *relax* argument of wcspih() and wcsbth() - accept PROJPn.

Refer to wcsbth() note 5.

WCSHDR_CD0i_0ja

#define WCSHDR_CD0i_0ja 0x00000020

WCSHDR_PC0i_0ja

#define WCSHDR_PC0i_0ja 0x00000040

WCSHDR_PV0i_0ma

#define WCSHDR_PV0i_0ma 0x00000080

WCSHDR_PS0i_0ma

#define WCSHDR_PS0i_0ma 0x00000100

WCSHDR_DOBSn

#define WCSHDR_DOBSn 0x00000200

Bit mask for wcspih() and wcsbth() - accept DOBSn.

Bit mask for the *relax* argument of wcspih() and wcsbth() - accept DOBSn.

Refer to wcsbth() note 5.

$WCSHDR_OBSGLBHn$

#define WCSHDR_OBSGLBHn 0x00000400

WCSHDR_RADECSYS

#define WCSHDR_RADECSYS 0x00000800

Bit mask for wcspih() and wcsbth() - accept RADECSYS.

Bit mask for the relax argument of wcspih() and wcsbth() - accept RADECSYS.

WCSHDR_EPOCHa

```
#define WCSHDR_EPOCHa 0x00001000
```

Bit mask for wcspih() and wcsbth() - accept EPOCHa.

Bit mask for the relax argument of wcspih() and wcsbth() - accept EPOCHa.

Refer to wcsbth() note 5.

WCSHDR_VSOURCE

```
#define WCSHDR_VSOURCE 0x00002000
```

Bit mask for wcspih() and wcsbth() - accept VSOURCEa.

Bit mask for the relax argument of wcspih() and wcsbth() - accept VSOURCEa.

Refer to wcsbth() note 5.

WCSHDR DATEREF

#define WCSHDR_DATEREF 0x00004000

WCSHDR_LONGKEY

#define WCSHDR_LONGKEY 0x00008000

Bit mask for wcspih() and wcsbth() - accept long forms of the alternate binary table and pixel list WCS keywords.

Bit mask for the *relax* argument of wcspih() and wcsbth() - accept long forms of the alternate binary table and pixel list WCS keywords.

Refer to wcsbth() note 5.

WCSHDR CNAMn

```
#define WCSHDR_CNAMn 0x00010000
```

Bit mask for wcspih() and wcsbth() - accept i CNAMn, TCNAMn, i CRDEn, TCRDEn, i CSYEn, TCSYEn.

Bit mask for the *relax* argument of wcspih() and wcsbth() - accept iCNAMn, iCRDEn, iCRDEn, iCSYEn, TCSYEn.

WCSHDR_AUXIMG

#define WCSHDR_AUXIMG 0x00020000

Bit mask for wcspih() and wcsbth() - allow the image-header form of an auxiliary WCS keyword to provide a default value for all images.

Bit mask for the *relax* argument of wcspih() and wcsbth() - allow the image-header form of an auxiliary WCS keyword with representation-wide scope to provide a default value for all images.

Refer to wcsbth() note 5.

WCSHDR ALLIMG

#define WCSHDR_ALLIMG 0x00040000

Bit mask for wcspih() and wcsbth() - allow the image-header form of all image header WCS keywords to provide a default value for all images.

Bit mask for the *relax* argument of wcspih() and wcsbth() - allow the image-header form of *all* image header WCS keywords to provide a default value for all image arrays in a binary table (n.b. not pixel list).

Refer to wcsbth() note 5.

WCSHDR_IMGHEAD

#define WCSHDR_IMGHEAD 0x00100000

Bit mask for wcsbth() - restrict to image header keywords only.

Bit mask for the keysel argument of wcsbth() - restrict keyword types considered to image header keywords only.

WCSHDR_BIMGARR

#define WCSHDR_BIMGARR 0x00200000

Bit mask for wcsbth() - restrict to binary table image array keywords only.

Bit mask for the *keysel* argument of wcsbth() - restrict keyword types considered to binary table image array keywords only.

WCSHDR_PIXLIST

#define WCSHDR_PIXLIST 0x00400000

Bit mask for wcsbth() - restrict to pixel list keywords only.

Bit mask for the keysel argument of wcsbth() - restrict keyword types considered to pixel list keywords only.

WCSHDO_none

```
#define WCSHDO_none 0x00000
```

Bit mask for wcshdo() - don't write any extensions.

Bit mask for the relax argument of wcshdo() - don't write any extensions.

Refer to the notes for wcshdo().

WCSHDO_all

```
#define WCSHDO_all 0x000FF
```

Bit mask for wcshdo() - write all extensions.

Bit mask for the *relax* argument of wcshdo() - write all extensions.

Refer to the notes for wcshdo().

WCSHDO safe

```
#define WCSHDO_safe 0x0000F
```

Bit mask for wcshdo() - write safe extensions only.

Bit mask for the relax argument of wcshdo() - write only extensions that are considered safe.

Refer to the notes for wcshdo().

WCSHDO_DOBSn

```
#define WCSHDO_DOBSn 0x00001
```

Bit mask for wcshdo() - write DOBSn.

Bit mask for the *relax* argument of wcshdo() - write DOBSn, the column-specific analogue of DATE-OBS for use in binary tables and pixel lists.

Refer to the notes for wcshdo().

WCSHDO_TPCn_ka

```
#define WCSHDO_TPCn_ka 0x00002
```

Bit mask for wcshdo() - write TPCn_ka.

Bit mask for the relax argument of wcshdo() - write TPCn_ka if less than eight characters instead of TPn_ka.

Refer to the notes for wcshdo().

WCSHDO_PVn_ma

#define WCSHDO_PVn_ma 0x00004

Bit mask for wcshdo() - write iPVn_ma, TPVn_ma, iPSn_ma, TPSn_ma.

Bit mask for the *relax* argument of wcshdo() - write iPVn_ma, TPVn_ma, iPSn_ma, if less than eight characters instead of iVn_ma, TVn_ma, iSn_ma, TSn_ma.

Refer to the notes for wcshdo().

WCSHDO CRPXna

#define WCSHDO_CRPXna 0x00008

Bit mask for wcshdo() - write jCRPXna, TCRPXna, iCDLTna, iCUNIna, iCUNIna, iCTYPna, iCTYPna, iCRVLna, TCRVLna.

Bit mask for the *relax* argument of wcshdo() - write jCRPXna, TCRPXna, iCDLTna, TCDLTna, iCUNIna, iCTYPna, iCTYPna, iCRVLna, iF less than eight characters instead of jCRPna, TCRPna, iCDEna, iCUNna, iCTYna, iCTYna, iCRVna, TCRVna.

Refer to the notes for wcshdo().

WCSHDO_CNAMna

#define WCSHDO_CNAMna 0x00010

Bit mask for wcshdo() - write iCNAMna, TCNAMna, iCRDEna, iCSYEna, TCSYEna.

Bit mask for the *relax* argument of wcshdo() - write iCNAMna, TCNAMna, iCRDEna, iCSYEna, iCSYEna, iCSYEna, iCSYEna, iCSYEna, iCSYEna, iCSYna, iCSYna,

Refer to the notes for wcshdo().

WCSHDO WCSNna

#define WCSHDO_WCSNna 0x00020

Bit mask for wcshdo() - write WCSNna instead of TWCSna

Bit mask for the *relax* argument of wcshdo() - write WCSNna instead of TWCSna.

Refer to the notes for wcshdo().

WCSHDO_P12

#define WCSHDO_P12 0x01000

6.29.4 Function Documentation

wcspih()

FITS WCS parser routine for image headers.

wcspih() is a high-level FITS WCS routine that parses an image header, either that of a primary HDU or of an image extension. All WCS keywords defined in Papers I, II, III, IV, and VII are recognized, and also those used by the AIPS convention and certain other keywords that existed in early drafts of the WCS papers as explained in wcsbth() note 5. wcspih() also handles keywords associated with non-standard distortion functions described in the prologue of dis.h.

Given a character array containing a FITS image header, **wcspih**() identifies and reads all WCS keywords for the primary coordinate representation and up to 26 alternate representations. It returns this information as an array of wcsprm structs.

wcspih() invokes wcstab() on each of the wcsprm structs that it returns.

Use wcsbth() in preference to wcspih() for FITS headers of unknown type; wcsbth() can parse image headers as well as binary table and pixel list headers, although it cannot handle keywords relating to distortion functions, which may only exist in an image header (primary or extension).

in,out	header	Character array containing the (entire) FITS image header from which to identify and construct the coordinate representations, for example, as might be obtained conveniently via the CFITSIO routine fits_hdr2str(). Each header "keyrecord" (formerly "card image") consists of exactly 80 7-bit ASCII printing characters in the range 0x20 to 0x7e (which excludes NUL, BS, TAB, LF, FF and CR) especially noting that the keyrecords are NOT null-terminated. For negative values of ctrl (see below), header[] is modified so that WCS keyrecords processed by wcspih() are removed from it.	
in	nkeyrec	Number of keyrecords in header[].	
in	relax	Degree of permissiveness:	

Parameters

in	ctrl	Error reporting and other control options for invalid WCS and other header keyrecords:
		0: Do not report any rejected header keyrecords.
		0. Do not report any rejected header keyrecords.
		1: Produce a one-line message stating the number of WCS keyrecords rejected (nreject).
		2: Report each rejected keyrecord and the reason why it was rejected.
		3: As above, but also report all non-WCS keyrecords that were discarded, and the number of coordinate representations (nwcs) found.
		 4: As above, but also report the accepted WCS keyrecords, with a summary of the number accepted as well as rejected.
		The report is written to stderr by default, or the stream set by wcsprintf_set(). For ctrl < 0, WCS keyrecords processed by wcspih() are removed from header[]:
		 -1: Remove only valid WCS keyrecords whose values were successfully extracted, nothing is reported.
		-2: As above, but also remove WCS keyrecords that were rejected, reporting each one and the reason that it was rejected.
		 -3: As above, and also report the number of coordinate representations (nwcs) found.
		 -11: Same as -1 but preserving global WCS-related keywords such as ' {DATE,MJD} -{OBS, BEG, AVG, END} ' and the other basic time-related keywords, and 'OBSGEO-{X,Y,Z,L,B,H}'.
		If any keyrecords are removed from header[] it will be null-terminated (NUL not being a legal FITS header character), otherwise it will contain its original complement of nkeyrec keyrecords and possibly not be null-terminated.
out	nreject	Number of WCS keywords rejected for syntax errors, illegal values, etc. Keywords not recognized as WCS keywords are simply ignored. Refer also to wcsbth() note 5.
out	nwcs	Number of coordinate representations found.
out	wcs	Pointer to an array of wcsprm structs containing up to 27 coordinate representations. Memory for the array is allocated by wcspih() which also invokes wcsini() for each struct to allocate memory for internal arrays and initialize their members to default values. Refer also to wcsbth() note 8. Note that wcsset() is not invoked on these structs. This allocated memory must be freed by the user, first by invoking wcsfree() for each
		struct, and then by freeing the array itself. A routine, wcsvfree(), is provided to do this (see below).

Returns

Status return value:

- 0: Success.
- 1: Null wcsprm pointer passed.
- 2: Memory allocation failed.
- 4: Fatal error returned by Flex parser.

Notes:

1. Refer to wcsbth() notes 1, 2, 3, 5, 7, and 8.

wcsbth()

FITS WCS parser routine for binary table and image headers.

wcsbth() is a high-level FITS WCS routine that parses a binary table header. It handles image array and pixel list WCS keywords which may be present together in one header.

As an extension of the FITS WCS standard, **wcsbth**() also recognizes image header keywords in a binary table header. These may be used to provide default values via an inheritance mechanism discussed in note 5 (c. \leftarrow f. WCSHDR_AUXIMG and WCSHDR_ALLIMG), or may instead result in wcsprm structs that are not associated with any particular column. Thus **wcsbth**() can handle primary image and image extension headers in addition to binary table headers (it ignores **NAXIS** and does not rely on the presence of the **TFIELDS** keyword).

All WCS keywords defined in Papers I, II, III, and VII are recognized, and also those used by the AIPS convention and certain other keywords that existed in early drafts of the WCS papers as explained in note 5 below.

wcsbth() sets the colnum or colax[] members of the wcsprm structs that it returns with the column number of an image array or the column numbers associated with each pixel coordinate element in a pixel list. wcsprm structs that are not associated with any particular column, as may be derived from image header keywords, have colnum == 0.

Note 6 below discusses the number of wcsprm structs returned by wcsbth(), and the circumstances in which image header keywords cause a struct to be created. See also note 9 concerning the number of separate images that may be stored in a pixel list.

The API to **wcsbth**() is similar to that of wcspih() except for the addition of extra arguments that may be used to restrict its operation. Like wcspih(), wcsbth() invokes wcstab() on each of the wcsprm structs that it returns.

i	in,out	header	Character array containing the (entire) FITS binary table, primary image, or image extension header from which to identify and construct the coordinate representations, for example, as might be obtained conveniently via the CFITSIO routine <code>fits_hdr2str()</code> . Each header "keyrecord" (formerly "card image") consists of exactly 80 7-bit ASCII printing characters in the range 0x20 to 0x7e (which excludes NUL, BS, TAB, LF, FF and CR) especially noting that the keyrecords are NOT null-terminated. For negative values of ctrl (see below), header[] is modified so that WCS keyrecords processed by <code>wcsbth()</code> are removed from it.
i	Ln	nkeyrec	Number of keyrecords in header[].
i	in	relax	Degree of permissiveness:

in	ctrl	Error reporting and other control options for invalid WCS and other header keyrecords:
		0: Do not report any rejected header keyrecords.
		1: Produce a one-line message stating the number of WCS keyrecords rejected (nreject).
		2: Report each rejected keyrecord and the reason why it was rejected.
		3: As above, but also report all non-WCS keyrecords that were discarded, and the number of coordinate representations (nwcs) found.
		 4: As above, but also report the accepted WCS keyrecords, with a summary of the number accepted as well as rejected.
		The report is written to stderr by default, or the stream set by wcsprintf_set(). For ctrl < 0, WCS keyrecords processed by wcsbth() are removed from header[]:
		 -1: Remove only valid WCS keyrecords whose values were successfully extracted, nothing is reported.
		 -2: Also remove WCS keyrecords that were rejected, reporting each one and the reason that it was rejected.
		 -3: As above, and also report the number of coordinate representations (nwcs) found.
		 -11: Same as -1 but preserving global WCS-related keywords such as ' {DATE,MJD} -{OBS, BEG, AVG, END} ' and the other basic time-related keywords, and 'OBSGEO-{X, Y, Z, L, B, H}'.
		If any keyrecords are removed from header[] it will be null-terminated (NUL not being a legal FITS header character), otherwise it will contain its original complement of nkeyrec keyrecords and possibly not be null-terminated.
in	keysel	Vector of flag bits that may be used to restrict the keyword types considered:
		WCSHDR_IMGHEAD: Image header keywords.
		WCSHDR_BIMGARR: Binary table image array.
		WCSHDR_PIXLIST: Pixel list keywords.
		If zero, there is no restriction.
		Keywords such as EQUI na or RFRQ na that are common to binary table image arrays and pixel lists (including WCSN na and TWCS na, as explained in note 4 below) are selected by both WCSHDR_BIMGARR and WCSHDR_PIXLIST. Thus if inheritance via WCSHDR_ALLIMG is enabled as discussed in note 5 and one of these shared keywords is present, then WCSHDR_IMGHEAD and WCSHDR_PIXLIST alone may be sufficient to cause the construction of coordinate descriptions for binary table image arrays.

Parameters

in	colsel	Pointer to an array of table column numbers used to restrict the keywords considered by wcsbth ().
		A null pointer may be specified to indicate that there is no restriction. Otherwise, the magnitude of cols[0] specifies the length of the array:
		• cols[0] > 0: the columns are included,
		• cols[0] < 0: the columns are excluded.
		For the pixel list keywords TP n_ka and TC n_ka (and TPC n_ka and TCD n_ka if WCSHDR_LONGKEY is enabled), it is an error for one column to be selected but not the other. This is unlike the situation with invalid keyrecords, which are simply rejected, because the error is not intrinsic to the header itself but arises in the way that it is processed.
out	nreject	Number of WCS keywords rejected for syntax errors, illegal values, etc. Keywords not recognized as WCS keywords are simply ignored, refer also to note 5 below.
out	nwcs	Number of coordinate representations found.
out	wcs	Pointer to an array of wcsprm structs containing up to 27027 coordinate representations, refer to note 6 below. Memory for the array is allocated by wcsbth() which also invokes wcsini() for each struct to allocate memory for internal arrays and initialize their members to default values. Refer also to note 8 below. Note that wcsset() is not invoked on these structs. This allocated memory must be freed by the user, first by invoking wcsfree() for each struct, and then by freeing the array itself. A routine, wcsvfree(), is provided to do this (see below).

Returns

Status return value:

- 0: Success.
- 1: Null wcsprm pointer passed.
- 2: Memory allocation failed.
- · 3: Invalid column selection.
- 4: Fatal error returned by Flex parser.

Notes:

- 1. wcspih() determines the number of coordinate axes independently for each alternate coordinate representation (denoted by the "a" value in keywords like CTYPEia) from the higher of
 - a NAXIS,
 - b wcsaxesa,
 - c The highest axis number in any parameterized WCS keyword. The keyvalue, as well as the keyword, must be syntactically valid otherwise it will not be considered.

If none of these keyword types is present, i.e. if the header only contains auxiliary WCS keywords for a particular coordinate representation, then no coordinate description is constructed for it.

wcsbth() is similar except that it ignores the NAXIS keyword if given an image header to process.

The number of axes, which is returned as a member of the wcsprm struct, may differ for different coordinate representations of the same image.

- 2. wcspih() and wcsbth() enforce correct FITS "keyword = value" syntax with regard to "= " occurring in columns 9 and 10.
 - However, they do recognize free-format character (NOST 100-2.0, Sect. 5.2.1), integer (Sect. 5.2.3), and floating-point values (Sect. 5.2.4) for all keywords.
- 3. Where CROTAn, CDi_ja, and PCi_ja occur together in one header wcspih() and wcsbth() treat them as described in the prologue to wcs.h.
- 4. WCS Paper I mistakenly defined the pixel list form of **WCSNAME**a as **TWCS**na instead of **WCSN**na; the 'T' is meant to substitute for the axis number in the binary table form of the keyword note that keywords defined in WCS Papers II, III, and VII that are not parameterized by axis number have identical forms for binary tables and pixel lists. Consequently **wcsbth()** always treats **WCSN**na and **TWCS**na as equivalent.
- 5. wcspih() and wcsbth() interpret the *relax* argument as a vector of flag bits to provide fine-grained control over what non-standard WCS keywords to accept. The flag bits are subject to change in future and should be set by using the preprocessor macros (see below) for the purpose.
 - WCSHDR_none: Don't accept any extensions (not even those in the errata). Treat non-conformant keywords in the same way as non-WCS keywords in the header, i.e. simply ignore them.
 - WCSHDR_all: Accept all extensions recognized by the parser.
 - WCSHDR_reject: Reject non-standard keyrecords (that are not otherwise explicitly accepted by one of the flags below). A message will optionally be printed on stderr by default, or the stream set by wcsprintf set(), as determined by the ctrl argument, and nreject will be incremented.

This flag may be used to signal the presence of non-standard keywords, otherwise they are simply passed over as though they did not exist in the header. It is mainly intended for testing conformance of a FITS header to the WCS standard.

Keyrecords may be non-standard in several ways:

- The keyword may be syntactically valid but with keyvalue of incorrect type or invalid syntax, or the keycomment may be malformed.
- The keyword may strongly resemble a WCS keyword but not, in fact, be one because it does not conform to the standard. For example, "CRPIX01" looks like a CRPIXja keyword, but in fact the leading zero on the axis number violates the basic FITS standard. Likewise, "LONPOLE2" is not a valid LONPOLEa keyword in the WCS standard, and indeed there is nothing the parser can sensibly do with it.
- Use of the keyword may be deprecated by the standard. Such will be rejected if not explicitly accepted via one of the flags below.
- WCSHDR_strict: As for WCSHDR_reject, but also reject AIPS-convention keywords and all other deprecated usage that is not explicitly accepted.
- WCSHDR_CROTAia: Accept CROTAia (wcspih()), iCROTna (wcsbth()), TCROTna (wcsbth()).
- WCSHDR_VELREFa: Accept VELREFa. wcspih() always recognizes the AIPS-convention keywords, CROTAn, EPOCH, and VELREF for the primary representation (a = ' ') but alternates are non-standard.
 wcsbth() accepts EPOCHa and VELREFa only if WCSHDR AUXIMG is also enabled.
- WCSHDR CD00i00j: Accept CD00i00j (wcspih()).
- WCSHDR PC00i00j: Accept PC00i00j (wcspih()).
- WCSHDR_PROJPn: Accept PROJPn (wcspih()). These appeared in early drafts of WCS Paper I+II (before they were split) and are equivalent to CDi_ja, PCi_ja, and PVi_ma for the primary representation (a = ' '). PROJPn is equivalent to PVi_ma with m = n ≤ 9, and is associated exclusively with the latitude axis.
- WCSHDR CD0i 0ja: Accept CD0i 0ja (wcspih()).
- WCSHDR PC0i 0ja: Accept PC0i 0ja (wcspih()).
- WCSHDR_PV0i_0ma: Accept PV0i_0ja (wcspih()).
- WCSHDR_PS0i_0ma: Accept PS0i_0ja (wcspih()). Allow the numerical index to have a leading zero in doubly- parameterized keywords, for example, PC01_01. WCS Paper I (Sects 2.1.2 & 2.1.4) explicitly disallows leading zeroes. The FITS 3.0 standard document (Sect. 4.1.2.1) states that the index in singly-parameterized keywords (e.g. CTYPEia) "shall not have leading zeroes", and later in Sect. 8.1 that "leading zeroes must not be used" on PVi_ma and PSi_ma. However, by an oversight, it is silent on PCi_ja and CDi_ja.

- WCSHDR_DOBSn (wcsbth() only): Allow DOBSn, the column-specific analogue of DATE-OBS. By an oversight this was never formally defined in the standard.
- WCSHDR_OBSGLBHn (wcsbth() only): Allow OBSGLn, OBSGBn, and OBSGHn, the column-specific
 analogues of OBSGEO-L, OBSGEO-B, and OBSGEO-H. By an oversight these were never formally
 defined in the standard.
- WCSHDR_RADECSYS: Accept RADECSYS. This appeared in early drafts of WCS Paper I+II and was subsequently replaced by RADESYSa.
 - wcsbth() accepts RADECSYS only if WCSHDR_AUXIMG is also enabled.
- WCSHDR_EPOCHa: Accept EPOCHa.
- WCSHDR_VSOURCE: Accept VSOURCEa or VSOUna (wcsbth()). This appeared in early drafts of WCS Paper III and was subsequently dropped in favour of ZSOURCEa and ZSOUna.
 wcsbth() accepts VSOURCEa only if WCSHDR AUXIMG is also enabled.
- #WCSHDR_<TT>DATEREF: Accept DATE-REF, MJD-REF, MJD-REFI, MJD-REFF, JDREF, JD-← REFI, and JD-REFF as synonyms for the standard keywords, DATEREF, MJDREF, MJDREFI, MJDREFF, JDREF, JDREFI, and JDREFF. The latter buck the pattern set by the other date keywords ({DATE,MJD}-{OBS,BEG,AVG,END}), thereby increasing the potential for confusion and error.
- WCSHDR_LONGKEY (wcsbth() only): Accept long forms of the alternate binary table and pixel list WCS keywords, i.e. with "a" non- blank. Specifically

j CRPX na	TCRPX na	\leftarrow	j CRPX n	j CRP na	TCRPXn	TCRP na	CRPIX ja

		••					
i CUNI na	TCUNI na	\leftarrow	i cuni n	i CUN na	TCUNIn	TCUN na	CUNIT ia
		:					
i CTYP na	TCTYP na	\leftarrow	i CTYP n	i CTY na	TCTYP n	TCTY na	CTYPE ia
		:					
i CRVL na	TCRVL na	\leftarrow	i CRVL n	i CRV na	TCRVL n	TCRV na	CRVAL ia
		:					
i PV n_ma	TPV n_ma	\leftarrow		i V n_ma		TV n_ma	PV i_ma
		:					
i PS n_ma	TPS n_ma	\leftarrow		i S n_ma		TS n_ma	PS i_ma
		:					

where the primary and standard alternate forms together with the image-header equivalent are shown rightwards of the colon.

The long form of these keywords could be described as quasi- standard. TPCn_ka, iPVn_ma, and TPVn_ma appeared by mistake in the examples in WCS Paper II and subsequently these and also TCDn_ka, iPSn_ma and TPSn_ma were legitimized by the errata to the WCS papers.

Strictly speaking, the other long forms are non-standard and in fact have never appeared in any draft of the WCS papers nor in the errata. However, as natural extensions of the primary form they are unlikely to be written with any other intention. Thus it should be safe to accept them provided, of course, that the resulting keyword does not exceed the 8-character limit.

If WCSHDR_CNAMn is enabled then also accept

i CNAM na	TCNAM na	\leftarrow	 i CNA na	 TCNA na	CNAME ia
		:			

i CRDE na	TCRDE na	\leftarrow	 i CRD na	 TCRD na	CRDER ia
		:			
i CSYE na	TCSYE na	\leftarrow	 i CSY na	 TCSY na	CSYER ia
		:			
TCZPH na	TCZPH na	\leftarrow	 TCZP na	 TCZP na	CZPHSia
		:			
i CPER na	TCPER na	\leftarrow	 i CPR na	 TCPR na	CPERIia
		:			

Note that **CNAME**ia, **CRDER**ia, **CSYER**ia, CZPHSia, CPERIia, and their variants are not used by WCSLIB but are stored in the wcsprm struct as auxiliary information.

- WCSHDR_CNAMn (wcsbth() only): Accept iCNAMn, iCRDEn, iCSYEn, TCZPHn, iCPERn, TCNAMn, TCRDEn, TCSYEn, TCZPHn, and TCPERn, i.e. with "a" blank. While non-standard, these are the obvious analogues of iCTYPn, TCTYPn, etc.
- WCSHDR_AUXIMG (wcsbth() only): Allow the image-header form of an auxiliary WCS keyword with representation-wide scope to provide a default value for all images. This default may be overridden by the column-specific form of the keyword.

For example, a keyword like **EQUINOX**a would apply to all image arrays in a binary table, or all pixel list columns with alternate representation "a" unless overridden by **EQUI**na.

Specifically the keywords are:

LONPOLE a	for LONP na	
LATPOLE a	for LATP na	
VELREF		 (No column-specific form.)
VELREF a		 Only if WCSHDR_VELREFa is set.

whose keyvalues are actually used by WCSLIB, and also keywords providing auxiliary information that is simply stored in the wcsprm struct:

WCSNAME a	for WCSN na	Or TWCS na (see below).
DATE-OBS	for DOBS n	
MJD-OBS	for MJDOB n	
RADESYS a	for RADE na	
RADECSYS	for RADE na	Only if WCSHDR_RADECSYS is set.
EPOCH		(No column-specific form.)
EPOCH a		Only if WCSHDR_EPOCHa is set.
EQUINOX a	for EQUI na	

where the image-header keywords on the left provide default values for the column specific keywords on the right.

Note that, according to Sect. 8.1 of WCS Paper III, and Sect. 5.2 of WCS Paper VII, the following are always inherited:

RESTFREQ	for RFRQ na
RESTFRQ a	for RFRQ na
RESTWAV a	for RWAV na

being those actually used by WCSLIB, together with the following auxiliary keywords, many of which do not have binary table equivalents

and therefore can only be inherited:

TIMESYS		
TREFPOS	for MJDA n	
TREFDIR	for MJDA n	
PLEPHEM	101 MODAII	
TIMEUNIT		
DATEREF		
MJDREF		
MJDREFI		
MJDREFF		
JDREF		
JDREFI		
JDREFF		
TIMEOFFS		
DATE-BEG		
DATE-AVG	for DAVG n	
DATE-END		
MJD-BEG		
MJD-AVG	for MJDA n	
MJD-END		
JEPOCH		
BEPOCH		
TSTART		
TSTOP		
XPOSURE		
TELAPSE		
TIMSYER		
TIMRDER		
TIMEDEL		
TIMEPIXR		
OBSGEO-X	for OBSGX n	
OBSGEO-Y	for OBSGY n	
OBSGEO-Z	for OBSGZ n	
OBSGEO-L	for OBSGL n	
OBSGEO-B	for OBSGB n	
OBSGEO-H	for OBSGH n	
OBSORBIT		
SPECSYSa	for SPEC na	
SSYSOBSa	for SOBS na	
VELOSYSa	for VSYS na	
VSOURCE a	for VSOU na	Only if WCSHDR_VSOURCE is set.
ZSOURCE a	for ZSOU na	
SSYSSRC a	for SSRC na	
VELANGL a	for VANG na	

Global image-header keywords, such as MJD-OBS, apply to all alternate representations, and would therefore provide a default value for all images in the header.

This auxiliary inheritance mechanism applies to binary table image arrays and pixel lists alike. Most of these keywords have no default value, the exceptions being <code>LONPOLE</code>a and <code>LATPOLE</code>a, and also <code>RADESYS</code>a and <code>EQUINOX</code>a which provide defaults for each other. Thus one potential

difficulty in using WCSHDR_AUXIMG is that of erroneously inheriting one of these four keywords.

Also, beware of potential inconsistencies that may arise where, for example, **DATE-OBS** is inherited, but **MJD-OBS** is overridden by **MJDOB**n and specifies a different time. Pairs in this category are:

The wcsfixi() routines datfix() and obsfix() are provided to check the consistency of these and other such pairs of keywords.

Unlike WCSHDR_ALLIMG, the existence of one (or all) of these auxiliary WCS image header keywords will not by itself cause a wcsprm struct to be created for alternate representation "a". This is because they do not provide sufficient information to create a non-trivial coordinate representation when used in conjunction with the default values of those keywords that are parameterized by axis number, such as CTYPEia.

• WCSHDR_ALLIMG (wcsbth() only): Allow the image-header form of *all* image header WCS keywords to provide a default value for all image arrays in a binary table (n.b. not pixel list). This default may be overridden by the column-specific form of the keyword.

For example, a keyword like \mathtt{CRPIX} ja would apply to all image arrays in a binary table with alternate representation "a" unless overridden by j \mathtt{CRP} na.

Specifically the keywords are those listed above for $\ensuremath{\mathsf{WCSHDR_AUXIMG}}$ plus

WCSAXESa for WCAXna

which defines the coordinate dimensionality, and the following keywords that are parameterized by axis number:

CRPIX ja	for j CRP na	
PC i_ja	for ij PC na	
CD i_ja	for ij CD na	
CDELT ia	for i CDE na	
CROTAi	for i CROT n	
CROTA ia		Only if WCSHDR_CROTAia is set.
CUNIT ia	for i CUN na	
CTYPE ia	for i CTY na	
CRVAL ia	for i CRV na	
PV i_ma	for i V n_ma	
PS i_ma	for i S n_ma	
CNAME ia	for i CNA na	
CRDER ia	for i CRD na	
CSYER ia	for i CSY na	
CZPHSia	for TCZP na	
CPERIia	for i CPR na	

where the image-header keywords on the left provide default values for the column specific keywords on the right.

This full inheritance mechanism only applies to binary table image arrays, not pixel lists, because in the latter case there is no well-defined association between coordinate axis number and column number (see note 9 below).

Note that **CNAME**ia, **CRDER**ia, **CSYER**ia, and their variants are not used by WCSLIB but are stored in the wcsprm struct as auxiliary information. Note especially that at least one wcsprm struct will be returned for each "a" found in one of the image header keywords listed above:

- If the image header keywords for "a" **are not** inherited by a binary table, then the struct will not be associated with any particular table column number and it is up to the user to provide an association.
- If the image header keywords for "a" are inherited by a binary table image array, then those keywords are considered to be "exhausted" and do not result in a separate wcsprm struct.

For example, to accept $CD00\mathrm{i}00\mathrm{j}$ and $PC00\mathrm{i}00\mathrm{j}$ and reject all other extensions, use

relax = WCSHDR_reject | WCSHDR_CD00i00j | WCSHDR_PC00i00j;

The parser always treats **EPOCH** as subordinate to **EQUINOX**a if both are present, and **VSOURCE**a is always subordinate to **ZSOURCE**a.

Likewise, **VELREF** is subordinate to the formalism of WCS Paper III, see spcaips().

Neither wcspih() nor wcsbth() currently recognize the AIPS-convention keywords ALTRPIX or ALTRVAL which effectively define an alternative representation for a spectral axis.

- 6. Depending on what flags have been set in its relax argument, wcsbth() could return as many as 27027 wcsprm structs:
 - Up to 27 unattached representations derived from image header keywords.
 - Up to 27 structs for each of up to 999 columns containing an image arrays.
 - Up to 27 structs for a pixel list.

Note that it is considered legitimate for a column to contain an image array and also form part of a pixel list, and in particular that **wcsbth**() does not check the **TFORM** keyword for a pixel list column to check that it is scalar.

In practice, of course, a realistic binary table header is unlikely to contain more than a handful of images.

In order for **wcsbth**() to create a wcsprm struct for a particular coordinate representation, at least one WCS keyword that defines an axis number must be present, either directly or by inheritance if WCSHDR_ALLIMG is set.

When the image header keywords for an alternate representation are inherited by a binary table image array via WCSHDR_ALLIMG, those keywords are considered to be "exhausted" and do not result in a separate wcsprm struct. Otherwise they do.

- Neither wcspih() nor wcsbth() check for duplicated keywords, in most cases they accept the last encountered.
- 8. wcspih() and wcsbth() use wcsnpv() and wcsnps() (refer to the prologue of wcs.h) to match the size of the pv[] and ps[] arrays in the wcsprm structs to the number in the header. Consequently there are no unused elements in the pv[] and ps[] arrays, indeed they will often be of zero length.
- 9. The FITS WCS standard for pixel lists assumes that a pixel list defines one and only one image, i.e. that each row of the binary table refers to just one event, e.g. the detection of a single photon or neutrino,

for which the device "pixel" coordinates are stored in separate scalar columns of the table.

In the absence of a standard for pixel lists — or even an informal description! — let alone a formal mechanism for identifying the columns containing pixel coordinates (as opposed to pixel values or metadata recorded at the time the photon or neutrino was detected), WCS Paper I discusses how the WCS keywords themselves may be used to identify them.

In practice, however, pixel lists have been used to store multiple images. Besides not specifying how to identify columns, the pixel list convention is also silent on the method to be used to associate table columns with image axes.

An additional shortcoming is the absence of a formal method for associating global binary-table WCS keywords, such as WCSNna or MJDOBn, with a pixel list image, whether one or several.

In light of these uncertainties, wcsbth() simply collects all WCS keywords for a particular pixel list coordinate representation (i.e. the "a" value in TCTYna) into one wcsprm struct. However, these alternates need not be associated with the same table columns and this allows a pixel list to contain up to 27 separate images. As usual, if one of these representations happened to contain more than two celestial axes, for example, then an error would result when wcsset() is invoked on it. In this case the "colsel" argument could be used to restrict the columns used to construct the representation so that it only contained one pair of celestial axes.

Global, binary-table WCS keywords are considered to apply to the pixel list image with matching alternate (e.g. the "a" value in LONPna or EQUIna), regardless of the table columns the image occupies. In other words, the column number is ignored (the "n" value in LONPna or EQUIna). This also applies for global, binary-table WCS keywords that have no alternates, such as MJDOBn and OBSGXn, which match all images in a pixel list. Take heed that this may lead to counterintuitive behaviour, especially where such a keyword references a column that does not store pixel coordinates, and moreso where the pixel list stores only a single image. In fact, as the column number, n, is ignored for such keywords, it would make no difference even if they referenced non-existent columns. Moreover, there is no requirement for consistency in the column numbers used for such keywords, even for OBSGYn, OBSGYn, and OBSGZn which are meant to define the elements of a coordinate vector. Although it would surely be perverse to construct a pixel list like this, such a situation may still arise in practice where columns are deleted from a binary table.

The situation with global, binary-table WCS keywords becomes potentially even more confusing when image arrays and pixel list images coexist in one binary table. In that case, a keyword such as **MJDOB**n may legitimately appear multiple times with n referencing different image arrays. Which then is the one that applies to the pixel list images? In this implementation, it is the last instance that appears in the header, whether or not it is also associated with an image array.

wcstab()

Tabular construction routine.

wcstab() assists in filling in the information in the wcsprm struct relating to coordinate lookup tables.

Tabular coordinates ('TAB') present certain difficulties in that the main components of the lookup table - the multidimensional coordinate array plus an index vector for each dimension - are stored in a FITS binary table extension (BINTABLE). Information required to locate these arrays is stored in PVi_ma and PSi_ma keywords in the image header.

wcstab() parses the PVi_ma and PSi_ma keywords associated with each 'TAB' axis and allocates memory in the wcsprm struct for the required number of tabprm structs. It sets as much of the tabprm struct as can be gleaned from the image header, and also sets up an array of wtbarr structs (described in the prologue of wtbarr.h) to assist in extracting the required arrays from the BINTABLE extension(s).

It is then up to the user to allocate memory for, and copy arrays from the BINTABLE extension(s) into the tabprm structs. A CFITSIO routine, fits_read_wcstab(), has been provided for this purpose, see getwcstab.h. wcsset() will automatically take control of this allocated memory, in particular causing it to be freed by wcsfree(); the user must not attempt to free it after wcsset() has been called.

Note that wcspih() and wcsbth() automatically invoke wcstab() on each of the wcsprm structs that they return.

Parameters

in, or	ıt	wcs	Coordinate transformation parameters (see below).
			wcstab() sets ntab, tab, nwtb and wtb, allocating memory for the tab and wtb arrays. This
			allocated memory will be freed automatically by wcsfree().

Returns

Status return value:

- 0: Success.
- 1: Null wcsprm pointer passed.
- · 2: Memory allocation failed.
- 3: Invalid tabular parameters.

For returns > 1, a detailed error message is set in wcsprm::err if enabled, see wcserr_enable().

wcsidx()

Index alternate coordinate representations.

wcsidx() returns an array of 27 indices for the alternate coordinate representations in the array of wcsprm structs returned by wcspih(). For the array returned by wcsbth() it returns indices for the unattached (colnum == 0) representations derived from image header keywords - use wcsbdx() for those derived from binary table image arrays or pixel lists keywords.

in	nwcs	Number of coordinate representations in the array.	
in	wcs	Pointer to an array of wcsprm structs returned by wcspih() or wcsbth().	

Parameters

out	alts	Index of each alternate coordinate representation in the array: alts[0] for the primary, alts[1] for
		'A', etc., set to -1 if not present.
		For example, if there was no 'P' representation then alts['P'-'A'+1] == -1;
		Otherwise, the address of its wcsprm struct would be wcs + alts['P'-'A'+1];

Returns

Status return value:

- 0: Success.
- 1: Null wcsprm pointer passed.

wcsbdx()

```
int wcsbdx (
                int nwcs,
                struct wcsprm ** wcs,
                int type,
                short alts[1000][28] )
```

Index alternate coordinate representions.

wcsbdx() returns an array of 999 x 27 indices for the alternate coordinate representions for binary table image arrays xor pixel lists in the array of wcsprm structs returned by wcsbth(). Use wcsidx() for the unattached representations derived from image header keywords.

in	nwcs	Number of coordinate representations in the array.	
in	wcs	Pointer to an array of wcsprm structs returned by wcsbth().	
in	type	Select the type of coordinate representation:	
		0: binary table image arrays,1: pixel lists.	
out	alts	Index of each alternate coordinate represention in the array: alts[col][0] for the primary, alts[col][1] for 'A', to alts[col][26] for 'Z', where col is the 1-relative column number, and col == 0 is used for unattached image headers. Set to -1 if not present. alts[col][27] counts the number of coordinate representations of the chosen type for each column. For example, if there was no 'P' represention for column 13 then alts[13]['P'-'A'+1] == -1; Otherwise, the address of its wcsprm struct would be wcs + alts[13]['P'-'A'+1];	

Returns

Status return value:

- · 0: Success.
- 1: Null wcsprm pointer passed.

wcsvfree()

```
int wcsvfree (
          int * nwcs,
          struct wcsprm ** wcs )
```

Free the array of wcsprm structs.

wcsvfree() frees the memory allocated by wcspih() or wcsbth() for the array of wcsprm structs, first invoking wcsfree() on each of the array members.

Parameters

in,out	nwcs	Number of coordinate representations found; set to 0 on return.
in,out	wcs	Pointer to the array of wcsprm structs; set to 0x0 on return.

Returns

Status return value:

- 0: Success.
- 1: Null wcsprm pointer passed.

wcshdo()

```
int wcshdo (
    int ctrl,
    struct wcsprm * wcs,
    int * nkeyrec,
    char ** header )
```

Write out a wcsprm struct as a FITS header.

wcshdo() translates a wcsprm struct into a FITS header. If the colnum member of the struct is non-zero then a binary table image array header will be produced. Otherwise, if the colax[] member of the struct is set non-zero then a pixel list header will be produced. Otherwise, a primary image or image extension header will be produced.

If the struct was originally constructed from a header, e.g. by wcspih(), the output header will almost certainly differ in a number of respects:

- The output header only contains WCS-related keywords. In particular, it does not contain syntactically-required keywords such as SIMPLE, NAXIS, BITPIX, or END.
- Elements of the PCi_ja matrix will be written if and only if they differ from the unit matrix. Thus, if the matrix is unity then no elements will be written.

- The redundant keywords MJDREF, JDREFI, JDREFI, JDREFF, all of which duplicate MJDREFI + MJDREFF, are never written. OBSGEO-[LBH] are not written if OBSGEO-[XYZ] are defined.
- Deprecated (e.g. CROTAn, RESTFREQ, VELREF, RADECSYS, EPOCH, VSOURCEa) or non-standard usage will be translated to standard (this is partially dependent on whether wcsfix() was applied).
- Additional keywords such as WCSAXESa, CUNITia, LONPOLEa and LATPOLEa may appear.
- · Quantities will be converted to the units used internally, basically SI with the addition of degrees.
- Floating-point quantities may be given to a different decimal precision.
- The original keycomments will be lost, although wcshdo() tries hard to write meaningful comments.
- · Keyword order will almost certainly be changed.

Keywords can be translated between the image array, binary table, and pixel lists forms by manipulating the colnum or colax[] members of the wcsprm struct.

in	ctrl	Vector of flag bits that controls the degree of permissiveness in departing from the published WCS standard, and also controls the formatting of floating-point keyvalues. Set it to zero to get the default behaviour. Flag bits for the degree of permissiveness:
		 WCSHDO_none: Recognize only FITS keywords defined by the published WCS standard.
		WCSHDO_all: Admit all recognized informal extensions of the WCS standard.
		Fine-grained control of the degree of permissiveness is also possible as explained in the notes below. As for controlling floating-point formatting, by default wcshdo () uses "%20.12G" for non-parameterized keywords such as LONPOLE a, and attempts to make the header more human-readable by using the same "f" format for all values of each of the following parameterized keywords: CRPIX ja, PC i_ja, and CDELT ia (n.b. excluding CRVAL ia). Each has the same field width and precision so that the decimal points line up. The precision, allowing for up to 15 significant digits, is chosen so that there are no excess trailing zeroes. A similar formatting scheme applies by default for distortion function parameters. However, where the values of, for example, CDELT ia differ by many orders of magnitude, the default formatting scheme may cause unacceptable loss of precision
		for the lower-valued keyvalues. Thus the default behaviour may be overridden: • WCSHDO_P12: Use "%20.12G" format for all floating- point keyvalues (12 significant digits).
		 WCSHDO_P13: Use "%21.13G" format for all floating- point keyvalues (13 significant digits).
		 WCSHDO_P14: Use "%22.14G" format for all floating- point keyvalues (14 significant digits).
		 WCSHDO_P15: Use "%23.15G" format for all floating- point keyvalues (15 significant digits).
		 WCSHDO_P16: Use "%24.16G" format for all floating- point keyvalues (16 significant digits).
		 WCSHDO_P17: Use "%25.17G" format for all floating- point keyvalues (17 significant digits).
		If more than one of the above flags are set, the highest number of significant digits prevails. In addition, there is an anciliary flag:
		WCSHDO_EFMT: Use "E" format instead of the default "G" format above.
		Note that excess trailing zeroes are stripped off the fractional part with "G" (which never occurs with "E"). Note also that the higher-precision options eat into the keycomment area. In this regard, WCSHDO_P14 causes minimal disruption with "G" format, while WCSHDO_P13 is appropriate with "E".
in,out	wcs	Pointer to a wcsprm struct containing coordinate transformation parameters. Will be initialized if necessary.
out	nkeyrec	Number of FITS header keyrecords returned in the "header" array.
out	header	Pointer to an array of char holding the header. Storage for the array is allocated by wcshdo () in blocks of 2880 bytes (32 x 80-character keyrecords) and must be freed by the user to avoid memory leaks. See wcsdealloc(). Each keyrecord is 80 characters long and is *NOT* null-terminated, so the first keyrecord starts at (*header)[0], the second at (*header)[80], etc.

Returns

Status return value (associated with wcs_errmsg[]):

- · 0: Success.
- · 1: Null wcsprm pointer passed.
- · 2: Memory allocation failed.
- · 3: Linear transformation matrix is singular.
- · 4: Inconsistent or unrecognized coordinate axis types.
- 5: Invalid parameter value.
- 6: Invalid coordinate transformation parameters.
- 7: Ill-conditioned coordinate transformation parameters.

For returns > 1, a detailed error message is set in wcsprm::err if enabled, see wcserr_enable().

Notes:

- 1. **wcshdo**() interprets the *relax* argument as a vector of flag bits to provide fine-grained control over what non-standard WCS keywords to write. The flag bits are subject to change in future and should be set by using the preprocessor macros (see below) for the purpose.
 - WCSHDO_none: Don't use any extensions.
 - WCSHDO_all: Write all recognized extensions, equivalent to setting each flag bit.
 - WCSHDO safe: Write all extensions that are considered to be safe and recommended.
 - WCSHDO_DOBSn: Write DOBSn, the column-specific analogue of DATE-OBS for use in binary tables
 and pixel lists. WCS Paper III introduced DATE-AVG and DAVGn but by an oversight DOBSn (the
 obvious analogy) was never formally defined by the standard. The alternative to using DOBSn is to write
 DATE-OBS which applies to the whole table. This usage is considered to be safe and is recommended.
 - WCSHDO TPCn ka: WCS Paper I defined
 - TPn_ka and TCn_ka for pixel lists

but WCS Paper II uses **TPC**n_ka in one example and subsequently the errata for the WCS papers legitimized the use of

- TPCn_ka and TCDn_ka for pixel lists

provided that the keyword does not exceed eight characters. This usage is considered to be safe and is recommended because of the non-mnemonic terseness of the shorter forms.

- WCSHDO_PVn_ma: WCS Paper I defined
 - iVn_ma and iSn_ma for bintables and
 - TVn_ma and TSn_ma for pixel lists

but WCS Paper II uses $i PV n_m a$ and $TPV n_m a$ in the examples and subsequently the errata for the WCS papers legitimized the use of

- iPVn_ma and iPSn_ma for bintables and
- TPVn_ma and TPSn_ma for pixel lists

provided that the keyword does not exceed eight characters. This usage is considered to be safe and is recommended because of the non-mnemonic terseness of the shorter forms.

- WCSHDO_CRPXna: For historical reasons WCS Paper I defined
 - jCRPXn, iCDLTn, iCUNIn, iCTYPn, and iCRVLn for bintables and
 - TCRPXn, TCDLTn, TCUNIn, TCTYPn, and TCRVLn for pixel lists

for use without an alternate version specifier. However, because of the eight-character keyword constraint, in order to accommodate column numbers greater than 99 WCS Paper I also defined

- jCRPna, iCDEna, iCUNna, iCTYna and iCRVna for bintables and
- TCRPna, TCDEna, TCUNna, TCTYna and TCRVna for pixel lists

for use with an alternate version specifier (the "a"). Like the PC, CD, PV, and PS keywords there is an obvious tendency to confuse these two forms for column numbers up to 99. It is very unlikely that any parser would reject keywords in the first set with a non-blank alternate version specifier so this usage is considered to be safe and is recommended.

- WCSHDO CNAMna: WCS Papers I and III defined
 - iCNAna, iCRDna, and iCSYna for bintables and
 - TCNAna, TCRDna, and TCSYna for pixel lists

By analogy with the above, the long forms would be

- iCNAMna, iCRDEna, and iCSYEna for bintables and
- TCNAMna, TCRDEna, and TCSYEna for pixel lists

Note that these keywords provide auxiliary information only, none of them are needed to compute world coordinates. This usage is potentially unsafe and is not recommended at this time.

WCSHDO_WCSNna: In light of wcsbth() note 4, write WCSNna instead of TWCSna for pixel lists. While wcsbth() treats WCSNna and TWCSna as equivalent, other parsers may not. Consequently, this usage is potentially unsafe and is not recommended at this time.

6.29.5 Variable Documentation

wcshdr_errmsg

```
const char * wcshdr_errmsg[] [extern]
```

Status return messages.

Error messages to match the status value returned from each function. Use wcs_errmsg[] for status returns from wcshdo().

00025 \star WCSLIB 8.3 - C routines that implement the FITS World Coordinate System
00026 \star (WCS) standard. Refer to the README file provided with WCSLIB for an
00027 * overview of the library.
00028 *
00029
```

```
00030 * Summary of the wcshdr routines
00031
00032 \star Routines in this suite are aimed at extracting WCS information from a FITS
00033 \star file. The information is encoded via keywords defined in
00034 *

00053 *
00054 \star These routines provide the high-level interface between the FITS file and
00055 * the WCS coordinate transformation routines.
00056 *
00057 \star Additionally, function wcshdo() is provided to write out the contents of a
00058 * wcsprm struct as a FITS header.
00059
00060 * Briefly, the anticipated sequence of operations is as follows:
00061 *
00062 *
          - 1: Open the FITS file and read the image or binary table header, e.g.
00063 *
               using CFITSIO routine fits_hdr2str().
00064 *
          - 2: Parse the header using wcspih() or wcsbth(); they will automatically
00065 *
               interpret 'TAB' header keywords using wcstab().
00066 *
00068 *
          - 3: Allocate memory for, and read 'TAB' arrays from the binary table
00069 *
               extension, e.g. using CFITSIO routine fits_read_wcstab() - refer to
00070 *
               the prologue of getwcstab.h. wcsset() will automatically take
00071 *
               control of this allocated memory, in particular causing it to be
00072 *
               freed by wcsfree().
00073 *
00074 *
          - 4: Translate non-standard WCS usage using wcsfix(), see wcsfix.h.
00075 *
00076 *
          - 5: Initialize wcsprm struct(s) using wcsset() and calculate coordinates
               using wcsp2s() and/or wcss2p(). Refer to the prologue of wcs.h for a description of these and other high-level WCS coordinate
00077 *
00078 *
00079 *
               transformation routines.
00080 *
00081 *
          - 6: Clean up by freeing memory with wcsvfree().
00082 *
00083 * In detail:
00084 *
00085 \star - wcspih() is a high-level FITS WCS routine that parses an image header. It
00086
         returns an array of up to 27 wcsprm structs on each of which it invokes
00087 *
          wcstab().
00088 *
00089 \star - wcsbth() is the analogue of wcspih() for use with binary tables; it
          handles image array and pixel list keywords. As an extension of the FITS WCS standard, it also recognizes image header keywords which may be used
00090 *
00091 *
00092 *
          to provide default values via an inheritance mechanism.
00093 *
00094 \star - wcstab() assists in filling in members of the wcsprm struct associated
00095 *
         with coordinate lookup tables ('TAB'). These are based on arrays stored
00096 *
          in a FITS binary table extension (BINTABLE) that are located by {\tt PVi\_ma}
00097 *
          keywords in the image header.
00098 *
00099 \star - wcsidx() and wcsbdx() are utility routines that return the index for a
00100 *
         specified alternate coordinate descriptor in the array of wcsprm structs
00101 *
          returned by wcspih() or wcsbth().
00102 *
00103 *
       - wcsvfree() deallocates memory for an array of wcsprm structs, such as
00104 *
          returned by wcspih() or wcsbth().
00105 *
00106 * - wcshdo() writes out a wcsprm struct as a FITS header.
00107 *
00108 *
00109 * wcspih() - FITS WCS parser routine for image headers
00110 * -
00111 \star wcspih() is a high-level FITS WCS routine that parses an image header,
00112 \star either that of a primary HDU or of an image extension. All WCS keywords
00113 \star defined in Papers I, II, III, IV, and VII are recognized, and also those
00114 \star used by the AIPS convention and certain other keywords that existed in early
00115 * drafts of the WCS papers as explained in wcsbth() note 5. wcspih() also
00116 * handles keywords associated with non-standard distortion functions described
```

```
00117 \star in the prologue of dis.h.
00119 \star Given a character array containing a FITS image header, wcspih() identifies
00120 \star and reads all WCS keywords for the primary coordinate representation and up
00121 \, \star \, \text{to} \, 26 alternate representations. It returns this information as an array of
00122 * wcsprm structs.
00124 * wcspih() invokes wcstab() on each of the wcsprm structs that it returns.
00125 *
00126 \star Use wcsbth() in preference to wcspih() for FITS headers of unknown type;
00127 \star wcsbth() can parse image headers as well as binary table and pixel list
00128 \star headers, although it cannot handle keywords relating to distortion
00129 \star functions, which may only exist in an image header (primary or extension).
00130 *
00131 * Given and returned:
00132 *
          header
                               Character array containing the (entire) FITS image
                  char[]
00133 *
                               header from which to identify and construct the
                               coordinate representations, for example, as might be obtained conveniently via the CFITSIO routine
00134 *
00135 *
00136 *
                               fits hdr2str().
00137 *
00138 *
                               Each header "keyrecord" (formerly "card image")
                               consists of exactly 80 7-bit ASCII printing characters
00139 *
                               in the range 0x20 to 0x7e (which excludes NUL, BS,
00140 *
00141 *
                               TAB, LF, FF and CR) especially noting that the
                               keyrecords are NOT null-terminated.
00142
00143
00144 *
                               For negative values of ctrl (see below), header[] is
00145 *
                               modified so that WCS keyrecords processed by wcspih()
00146 *
                               are removed from it.
00147 *
00148 * Given:
00149 *
                               Number of keyrecords in header[].
         nkeyrec
00150 *
00151 *
          relax
                               Degree of permissiveness:
                    int
                                 0: Recognize only FITS keywords defined by the
00152 *
                                    published WCS standard.
00153 *
                                 WCSHDR_all: Admit all recognized informal
00154 *
00155 *
                                    extensions of the WCS standard.
00156 *
                               Fine-grained control of the degree of permissiveness
00157 *
                               is also possible as explained in wcsbth() note 5.
00158 *
00159 *
                               Error reporting and other control options for invalid
          ctrl
                    int
00160 *
                               WCS and other header keyrecords:
                                   0: Do not report any rejected header keyrecords.
00161 *
00162 *
                                   1: Produce a one-line message stating the number
00163 *
                                      of WCS keyrecords rejected (nreject).
00164 *
                                   2: Report each rejected keyrecord and the reason
00165 *
                                      why it was rejected.
00166 *
                                    3: As above, but also report all non-WCS
00167 *
                                      keyrecords that were discarded, and the number
00168 *
                                      of coordinate representations (nwcs) found.
00169 *
                                   4: As above, but also report the accepted WCS
00170 *
                                      keyrecords, with a summary of the number
00171 *
                                      accepted as well as rejected.
                               The report is written to stderr by default, or the
00172 *
                               stream set by wcsprintf_set().
00174 *
00175 *
                               For ctrl < 0, WCS keyrecords processed by wcspih()
                               are removed from header[]:
00176 *
                                  -1: Remove only valid WCS keyrecords whose values
00177 *
00178 *
                                      were successfully extracted, nothing is
00179 *
                                      reported.
                                  -2: As above, but also remove WCS keyrecords that
00180 *
00181 *
                                       were rejected, reporting each one and the
00182 *
                                      reason that it was rejected.
00183 *
                                  -3: As above, and also report the number of
00184 *
                                      coordinate representations (nwcs) found.
                                 -11: Same as -1 but preserving global WCS-related
00185 *
                                      keywords such as '{DATE, MJD}-{OBS, BEG, AVG, END}'
00186 *
00187 *
                                       and the other basic time-related keywords, and
00188 *
                                       'OBSGEO-{X,Y,Z,L,B,H}'.
00189 *
                               If any keyrecords are removed from header[] it will
                               be null-terminated (NUL not being a legal FITS header
00190 *
00191 *
                               character), otherwise it will contain its original
00192
                               complement of nkeyrec keyrecords and possibly not be
00193 *
                               null-terminated.
00194 *
00195 * Returned:
00196 *
                               Number of WCS keywords rejected for syntax errors.
          nreject
                    int.*
00197 *
                               illegal values, etc. Keywords not recognized as WCS
00198 *
                               keywords are simply ignored. Refer also to wcsbth()
00199 *
00200 *
00201 *
          nwcs
                    int*
                               Number of coordinate representations found.
00202 *
00203 *
                    struct wcsprm**
          WCS
```

```
00204 *
                               Pointer to an array of wcsprm structs containing up to
00205 *
                               27 coordinate representations.
00206 *
00207 *
                               Memory for the array is allocated by wcspih() which
00208 *
                               also invokes wcsini() for each struct to allocate
00209 *
                               memory for internal arrays and initialize their
00210
                               members to default values. Refer also to wcsbth()
00211
                               note 8. Note that wcsset() is not invoked on these
00212 *
                               structs.
00213 *
00214 *
                               This allocated memory must be freed by the user, first
                               by invoking wcsfree() for each struct, and then by
00215 *
00216 *
                               freeing the array itself. A routine, wcsvfree(), is
                               provided to do this (see below).
00217
00218 *
00219 * Function return value:
00220 *
                    int
                               Status return value:
00221 *
                                 0: Success.
                                 1: Null wcsprm pointer passed.
00223 *
                                 2: Memory allocation failed.
00224 *
                                 4: Fatal error returned by Flex parser.
00225 *
00226 * Notes:
00227 * 1: Refer to wcsbth() notes 1, 2, 3, 5, 7, and 8.
00228 *
00229
00230 * wcsbth() - FITS WCS parser routine for binary table and image headers
00231 * -
00232 \star wcsbth() is a high-level FITS WCS routine that parses a binary table header.
00233 \star It handles image array and pixel list WCS keywords which may be present
00234 * together in one header.
00235 *
00236 \star As an extension of the FITS WCS standard, wcsbth() also recognizes image
00237 \star header keywords in a binary table header. These may be used to provide
00238 \star default values via an inheritance mechanism discussed in note 5 (c.f.
00239 \star WCSHDR_AUXIMG and WCSHDR_ALLIMG), or may instead result in wcsprm structs
00240 \star that are not associated with any particular column. Thus wcsbth() can 00241 \star handle primary image and image extension headers in addition to binary table
00242 \star headers (it ignores NAXIS and does not rely on the presence of the TFIELDS
00243 * keyword).
00244 *
00245 * All WCS keywords defined in Papers I, II, III, and VII are recognized, and
00246 * also those used by the ATPS convention and certain other keywords that
00247 * existed in early drafts of the WCS papers as explained in note 5 below.
00248 *
00249 \star wcsbth() sets the colnum or colax[] members of the wcsprm structs that it
00250 \star returns with the column number of an image array or the column numbers
00251 \star associated with each pixel coordinate element in a pixel list. wcsprm
00252 \star structs that are not associated with any particular column, as may be
00253 * derived from image header keywords, have colnum == 0.
00255 \star Note 6 below discusses the number of wcsprm structs returned by wcsbth(),
00256 \star and the circumstances in which image header keywords cause a struct to be
00257 \star created. See also note 9 concerning the number of separate images that may
00258 \star be stored in a pixel list.
00259 *
00260 \star The API to wcsbth() is similar to that of wcspih() except for the addition
00261 \star of extra arguments that may be used to restrict its operation. Like
00262 * wcspih(), wcsbth() invokes wcstab() on each of the wcsprm structs that it
00263 * returns.
00264 *
00265 * Given and returned:
00266 *
          header
                               Character array containing the (entire) FITS binary
                    char[]
                               table, primary image, or image extension header from
00267 *
00268 *
                               which to identify and construct the coordinate
00269 *
                               representations, for example, as might be obtained
00270 *
                               conveniently via the CFITSIO routine fits_hdr2str().
00271 *
00272 *
                               Each header "keyrecord" (formerly "card image")
                               consists of exactly 80 7-bit ASCII printing
00273 *
00274 *
                               characters in the range 0x20 to 0x7e (which excludes
00275
                               NUL, BS, TAB, LF, FF and CR) especially noting that
00276 *
                               the keyrecords are NOT null-terminated.
00277 *
00278 *
                               For negative values of ctrl (see below), header[] is
00279
                               modified so that WCS keyrecords processed by wcsbth()
00280 *
                               are removed from it.
00281 *
00282 * Given:
00283 *
                               Number of keyrecords in header[].
         nkevrec
                    int
00284 *
00285 *
                               Degree of permissiveness:
          relax
                    int
00286 *
                                 0: Recognize only FITS keywords defined by the
00287 *
                                    published WCS standard.
00288 *
                                 WCSHDR_all: Admit all recognized informal
00289 *
                                    extensions of the WCS standard.
00290 *
                               Fine-grained control of the degree of permissiveness
```

```
00291 *
                                is also possible, as explained in note 5 below.
00292 *
00293 *
          ctrl
                                Error reporting and other control options for invalid
                     int
00294 *
                                WCS and other header keyrecords:
00295 *
                                    0: Do not report any rejected header keyrecords.
00296 *
                                    1: Produce a one-line message stating the number
                                       of WCS keyrecords rejected (nreject).
00297
00298
                                    2: Report each rejected keyrecord and the reason
00299 *
                                       why it was rejected.
00300 *
                                    3: As above, but also report all non-WCS
00301 *
                                       keyrecords that were discarded, and the number
00302 *
                                       of coordinate representations (nwcs) found.
00303 *
                                    4: As above, but also report the accepted WCS
00304 *
                                       keyrecords, with a summary of the number
00305 *
                                       accepted as well as rejected.
00306 *
                                The report is written to stderr by default, or the
00307 *
                                stream set by wcsprintf_set().
00308 *
00309
                                For ctrl < 0, WCS keyrecords processed by wcsbth()
00310 *
                                are removed from header[]:
00311 *
                                   -1: Remove only valid WCS keyrecords whose values
00312 *
                                       were successfully extracted, nothing is
00313 *
                                       reported.
                                   -2: Also remove WCS keyrecords that were rejected,
00314 *
00315 *
                                       reporting each one and the reason that it was
00316
                                       rejected.
00317 *
                                   -3: As above, and also report the number of
00318 *
                                       coordinate representations (nwcs) found.
                                  -11: Same as -1 but preserving global WCS-related keywords such as '{DATE,MJD}-{OBS,BEG,AVG,END}'
00319 *
00320 *
00321 >
                                       and the other basic time-related keywords, and
00322 *
                                        'OBSGEO-{X,Y,Z,L,B,H}'.
00323 *
                                If any keyrecords are removed from header[] it will
00324 *
                                be null-terminated (NUL not being a legal FITS header
00325 *
                                character), otherwise it will contain its original
                                complement of nkeyrec keyrecords and possibly not be
00326 *
00327 *
                                null-terminated.
00328 *
00329 *
          keysel
                                Vector of flag bits that may be used to restrict the
00330 *
                                keyword types considered:
00331 *
                                  WCSHDR_IMGHEAD: Image header keywords.
                                 WCSHDR_BIMGARR: Binary table image array. WCSHDR_PIXLIST: Pixel list keywords.
00332 *
00333 *
00334 *
                                If zero, there is no restriction.
00335
00336 *
                                Keywords such as EQUIna or RFRQna that are common to
00337 *
                                binary table image arrays and pixel lists (including
00338 *
                                WCSNna and TWCSna, as explained in note 4 below) are
                                selected by both WCSHDR_BIMGARR and WCSHDR_PIXLIST.
00339 *
                                Thus if inheritance via WCSHDR_ALLIMG is enabled as
00340 *
00341 +
                                discussed in note 5 and one of these shared keywords
00342 *
                                is present, then WCSHDR_IMGHEAD and WCSHDR_PIXLIST
00343 *
                                alone may be sufficient to cause the construction of
00344 *
                                coordinate descriptions for binary table image arrays.
00345 *
00346 *
          colsel
                    int*
                                Pointer to an array of table column numbers used to
00347 *
                                restrict the keywords considered by wcsbth().
00348 *
00349 *
                                A null pointer may be specified to indicate that there
00350 *
                                is no restriction. Otherwise, the magnitude of
                                cols[0] specifies the length of the array:
00351 *
00352 *
                                  cols[0] > 0: the columns are included,
00353 *
                                  cols[0] < 0: the columns are excluded.
00354
00355
                                For the pixel list keywords TPn_ka and TCn_ka (and
00356 *
                                TPCn_ka and TCDn_ka if WCSHDR_LONGKEY is enabled), it
                                is an error for one column to be selected but not the
00357 *
00358 *
                                other. This is unlike the situation with invalid
00359
                                keyrecords, which are simply rejected, because the
00360
                                error is not intrinsic to the header itself but
00361 *
                                arises in the way that it is processed.
00362 *
00363 * Returned:
                                Number of WCS keywords rejected for syntax errors,
00364 *
          nreject
                     int*
00365 *
                                illegal values, etc. Keywords not recognized as WCS
00366 *
                                keywords are simply ignored, refer also to note 5
00367 *
00368 *
00369 *
          nwcs
                     int*
                               Number of coordinate representations found.
00370 *
00371 *
          WCS
                     struct wcsprm**
00372 *
                                Pointer to an array of wcsprm structs containing up
00373 *
                                to 27027 coordinate representations, refer to note 6
00374 *
                                below.
00375 *
                               Memory for the array is allocated by wcsbth() which also invokes wcsini() for each struct to allocate
00376 *
00377 *
```

```
memory for internal arrays and initialize their
00379 *
                                members to default values. Refer also to note 8
                                below. Note that wcsset() is not invoked on these
00380 *
00381 *
                                structs.
00382 *
00383 *
                                This allocated memory must be freed by the user, first
                                by invoking wcsfree() for each struct, and then by freeing the array itself. A routine, wcsvfree(), is
00384
00385
00386 *
                                provided to do this (see below).
00387 *
00388 * Function return value:
00389 *
                    int
                                Status return value:
00390 *
                                  0: Success.
00391 *
                                  1: Null wcsprm pointer passed.
00392 *
                                  2: Memory allocation failed.
00393 *
                                  3: Invalid column selection.
00394 *
                                  4: Fatal error returned by Flex parser.
00395 *
00396 * Notes:
00397 *
         1: wcspih() determines the number of coordinate axes independently for
              each alternate coordinate representation (denoted by the "a" value in
00398 *
00399 *
              keywords like CTYPEia) from the higher of
00400 *
00401 *
                a: NAXIS.
00402 *
                b: WCSAXESa,
00403 *
               c: The highest axis number in any parameterized WCS keyword. The
                   keyvalue, as well as the keyword, must be syntactically valid
00404 *
00405 *
                   otherwise it will not be considered.
00406 *
00407 *
             If none of these keyword types is present, i.e. if the header only contains auxiliary WCS keywords for a particular coordinate
00408 *
00409 *
              representation, then no coordinate description is constructed for it.
00410 *
00411 *
              wcsbth() is similar except that it ignores the NAXIS keyword if given
00412 *
             an image header to process.
00413 *
00414 *
              The number of axes, which is returned as a member of the wcsprm
              struct, may differ for different coordinate representations of the
00416 *
             same image.
00417 *
00418 *
          2: wcspih() and wcsbth() enforce correct FITS "keyword = value" syntax
00419 *
              with regard to "= " occurring in columns 9 and 10.
00420 *
00421 *
              However, they do recognize free-format character (NOST 100-2.0,
00422 *
              Sect. 5.2.1), integer (Sect. 5.2.3), and floating-point values
00423 *
              (Sect. 5.2.4) for all keywords.
00424 *
00425 *
          3: Where CROTAn, CDi_ja, and PCi_ja occur together in one header wcspih()
00426 *
              and wcsbth() treat them as described in the proloque to wcs.h.
00427
          4: WCS Paper I mistakenly defined the pixel list form of WCSNAMEa as TWCSna instead of WCSNna; the 'T' is meant to substitute for the axis
00428 *
00429 *
00430 *
              number in the binary table form of the keyword - note that keywords
              defined in WCS Papers II, III, and VII that are not parameterized by axis number have identical forms for binary tables and pixel lists.
00431 *
00432 *
00433 *
              Consequently wcsbth() always treats WCSNna and TWCSna as equivalent.
00434 *
00435 *
          5: wcspih() and wcsbth() interpret the "relax" argument as a vector of
              flag bits to provide fine-grained control over what non-standard \ensuremath{\mathsf{WCS}}
00436 *
00437 *
              keywords to accept. The flag bits are subject to change in future and
              should be set by using the preprocessor macros (see below) for the
00438 *
00439 *
              purpose.
00440 *
00441 *
              - WCSHDR_none: Don't accept any extensions (not even those in the
00442 *
                       errata). Treat non-conformant keywords in the same way as
00443 *
                      non-WCS keywords in the header, i.e. simply ignore them.
00444 *
00445 *
              - WCSHDR all: Accept all extensions recognized by the parser.
00446 *
              - WCSHDR_reject: Reject non-standard keyrecords (that are not otherwise
00448 *
                      explicitly accepted by one of the flags below). A message will
00449 *
                      optionally be printed on stderr by default, or the stream set
00450 *
                      by wcsprintf_set(), as determined by the ctrl argument, and
00451 *
                      nreject will be incremented.
00452 *
00453 *
                      This flag may be used to signal the presence of non-standard
00454 *
                       keywords, otherwise they are simply passed over as though they
00455 *
                      did not exist in the header. It is mainly intended for testing
00456 *
                      conformance of a FITS header to the WCS standard.
00457 *
00458 *
                      Keyrecords may be non-standard in several ways:
00459 *
                         - The keyword may be syntactically valid but with keyvalue of
00460 *
00461 *
                           incorrect type or invalid syntax, or the keycomment may be
00462 *
                           malformed.
00463 *
00464 *
                        - The keyword may strongly resemble a WCS keyword but not, in
```

```
00465 *
                             fact, be one because it does not conform to the standard.
                             For example, "CRPIX01" looks like a CRPIXja keyword, but in
00466 *
                             fact the leading zero on the axis number violates the basic FITS standard. Likewise, "LONPOLE2" is not a valid
00467 *
00468 *
                             LONPOLEa keyword in the WCS standard, and indeed there is
00469 *
00470 *
                             nothing the parser can sensibly do with it.
00471
00472 *
                          - Use of the keyword may be deprecated by the standard.
00473 *
                             will be rejected if not explicitly accepted via one of the
00474 *
                             flags below.
00475 *
              - \mbox{WCSHDR\_strict:} As for \mbox{WCSHDR\_reject,} but also reject AIPS-convention
00476 *
00477 *
                        keywords and all other deprecated usage that is not explicitly
00478 *
00479 *
00480 *
               - WCSHDR_CROTAia: Accept CROTAia (wcspih()),
00481 *
                                            iCROTna (wcshth()).
00482 *
                                            TCROTna (wcsbth()).
               - WCSHDR_VELREFa: Accept VELREFa.
00484 *
                        wcspih() always recognizes the AIPS-convention keywords,
                        CROTAn, EPOCH, and VELREF for the primary representation (a = '\ ') but alternates are non-standard.
00485 *
00486 *
00487 *
                        wcsbth() accepts EPOCHa and VELREFa only if WCSHDR_AUXIMG is
00488 *
00489 *
                        also enabled.
00490 *
00491 *
               - WCSHDR_CD00i00j: Accept CD00i00j (wcspih()).
00492 *
               - WCSHDR_PC00i00j: Accept PC00i00j (wcspih())
00493 *
              - WCSHDR_PROJPn: Accept PROJPn
                                                       (wcspih()).
00494 *
                        These appeared in early drafts of WCS Paper I+II (before they
00495 *
                        were split) and are equivalent to CDi_ja, PCi_ja, and PVi_ma for the primary representation (a = ^{\prime} ^{\prime}). PROJPn is
00496 *
00497 *
                        equivalent to PVi_ma with m = n \le 9, and is associated
00498 *
                        exclusively with the latitude axis.
00499 *
              - WCSHDR_CD0i_0ja: Accept CD0i_0ja (wcspih()).
00500 *
              - WCSHDR_PC0i_0ja: Accept PC0i_0ja (wcspih()).
- WCSHDR_PV0i_0ma: Accept PV0i_0ja (wcspih()).
00501 *
00503 *
               - WCSHDR_PS0i_Oma: Accept PS0i_0ja (wcspih()).
00504 *
                        Allow the numerical index to have a leading zero in doubly-
00505 *
                        parameterized keywords, for example, PC01_01. WCS Paper I
                         (Sects 2.1.2 & 2.1.4) explicitly disallows leading zeroes.
00506 *
00507 *
                        The FITS 3.0 standard document (Sect. 4.1.2.1) states that the
                        index in singly-parameterized keywords (e.g. CTYPEia)
00508 *
                                                                                         'shall
                        not have leading zeroes", and later in Sect. 8.1 that "leading zeroes must not be used" on PVi_ma and PSi_ma. However, by an
00509 *
00510 *
00511 *
                        oversight, it is silent on PCi_ja and CDi_ja.
00512 *
              - WCSHDR_DOBSn (wcsbth() only): Allow DOBSn, the column-specific analogue of DATE-OBS. By an oversight this was never formally
00513 *
00514 *
00515 *
                        defined in the standard.
00516 *
00517 *
              - WCSHDR_OBSGLBHn (wcsbth() only): Allow OBSGLn, OBSGBn, and OBSGHn,
00518 *
                        the column-specific analogues of OBSGEO-L, OBSGEO-B, and
00519 *
                        \ensuremath{\mathsf{OBSGEO-H.}} By an oversight these were never formally defined in
00520 *
                        the standard.
00521 *
00522 *
               - WCSHDR_RADECSYS: Accept RADECSYS. This appeared in early drafts of
00523 *
                        WCS Paper I+II and was subsequently replaced by RADESYSa.
00524 *
00525 *
                        wcsbth() accepts RADECSYS only if WCSHDR_AUXIMG is also
00526 *
                        enabled.
00527 *
00528 *
               - WCSHDR_EPOCHa: Accept EPOCHa.
00529 *
00530 *
              - WCSHDR_VSOURCE: Accept VSOURCEa or VSOUna (wcsbth()). This appeared
                        in early drafts of WCS Paper III and was subsequently dropped
00531 *
                        in favour of ZSOURCEa and ZSOUna.
00532 *
00533 *
                        wcsbth() accepts VSOURCEa only if WCSHDR_AUXIMG is also
00535 *
00536 *
00537 *
              - WCSHDR_DATEREF: Accept DATE-REF, MJD-REF, MJD-REFI, MJD-REFF, JDREF,
00538 *
                        \ensuremath{\mathsf{JD}}\xspace\ensuremath{\mathsf{-REFI}}\xspace , and \ensuremath{\mathsf{JD}}\xspace\ensuremath{\mathsf{-REFI}}\xspace as synonyms for the standard keywords,
                        DATEREF, MJDREF, MJDREFI, MJDREFF, JDREF, JDREFI, and JDREFF. The latter buck the pattern set by the other date keywords
00539 *
00540 *
00541 *
                        ({DATE, MJD}-{OBS, BEG, AVG, END}), thereby increasing the
00542 *
                        potential for confusion and error.
00543 *
00544 *
              - WCSHDR_LONGKEY (wcsbth() only): Accept long forms of the alternate
                        binary table and pixel list WCS keywords, i.e. with "a" non-
00545 *
                        blank. Specifically

                                                  wcsprm struct as auxiliary information.
00586 *
                              - WCSHDR_CNAMn (wcsbth() only): Accept iCNAMn, iCRDEn, iCSYEn, iCZPHn,
00587 *
                                                 iCPERR, TCNAMN, TCRDEn, TCSYEn, TCZPHn, and TCPERR, i.e. with "a" blank. While non-standard, these are the obvious analogues
00588 *
00590 *
                                                 of iCTYPn, TCTYPn, etc.
00591 *
00592 *
                              - WCSHDR_AUXIMG (wcsbth() only): Allow the image-header form of an
                                                 auxiliary WCS keyword with representation-wide scope to
00593 *
00594 *
                                                 provide a default value for all images. This default may be
                                                 overridden by the column-specific form of the keyword.
00595 *
00596 *
00597 *
                                                 For example, a keyword like EQUINOXa would apply to all image
                                                 arrays in a binary table, or all pixel list columns with alternate representation "a" unless overridden by EQUIna.
00598 *
00599 *
00600 *
00601 *
                                                 Specifically the keywords are:
00602 *
00603 #
                                                      LONPOLEa for LONPna
00604 #
                                                      LATPOLEa for LATPna
00605 #
                                                      WELREE
                                                                                                          ... (No column-specific form.)
00606 #
                                                                                                           ... Only if WCSHDR_VELREFa is set.
                                                      VELREFa
00607 *
                                                 whose keyvalues are actually used by WCSLIB, and also keywords
00609 *
                                                 providing auxiliary information that is simply stored in the
00610 *
                                                  wcsprm struct:
00611 *
                                                      WCSNAMEa for WCSNna \dots Or TWCSna (see below).
00612 #
00613 #

00680 #
                       VSOURCEa for VSOUna ... Only if WCSHDR_VSOURCE is set.
                       ZSOURCEa for ZSOUna
00681 #
00682 #
                       SSYSSRCa for SSRCna
                       VELANGLa for VANGna
00684 *
00685 *
                     Global image-header keywords, such as MJD-OBS, apply to all
00686 *
                     alternate representations, and would therefore provide a
00687 *
                     default value for all images in the header.
00688 *
00689 *
                     This auxiliary inheritance mechanism applies to binary table
00690 *
                     image arrays and pixel lists alike. Most of these keywords
00691 *
                     have no default value, the exceptions being LONPOLEa and
00692 *
                     {\tt LATPOLEa,} and also RADESYSa and EQUINOXa which provide
00693 *
                     defaults for each other. Thus one potential difficulty in
00694 *
                     using WCSHDR_AUXIMG is that of erroneously inheriting one of
                     these four keywords.
00696 *
00697 *
                     Also, beware of potential inconsistencies that may arise where,
00698 *
                     for example, DATE-OBS is inherited, but MJD-OBS is overridden
00699 *
                     by MJDOBn and specifies a different time. Pairs in this
00700 *
                     category are:
00701 *
00702 =
                                                              MJD-OBS/MJDOBn
                                                versus
00703 =
                           DATE-AVG/DAVGn
                                                              MJD-AVG/MJDAn
00704 =
                           RESTFRQa/RFRQna
                                                versus
                                                            RESTWAVa/RWAVna
00705 =
                       OBSGEO-[XYZ]/OBSG[XYZ]n versus OBSGEO-[LBH]/OBSG[LBH]n
00706 *
00707 *
                     The wcsfixi() routines datfix() and obsfix() are provided to
00708 *
                     check the consistency of these and other such pairs of
00709 *
00710 *
00711 *
                     Unlike WCSHDR_ALLIMG, the existence of one (or all) of these
00712 *
                     auxiliary WCS image header keywords will not by itself cause a
00713 *
                     wcsprm struct to be created for alternate representation "a".
00714 *
                     This is because they do not provide sufficient information to
00715 *
                     create a non-trivial coordinate representation when used in
00716 *
                     conjunction with the default values of those keywords that are
00717 *
                     parameterized by axis number, such as CTYPEia.
00718 *
00719 *
             - WCSHDR_ALLIMG (wcsbth() only): Allow the image-header form of *all*
                     image header WCS keywords to provide a default value for all
00721 *
                     image arrays in a binary table (n.b. not pixel list). This
00722 *
                     default may be overridden by the column-specific form of the
00723 *
                     keyword.
00724 *
00725 *
                     For example, a keyword like CRPIXja would apply to all image
```

```
arrays in a binary table with alternate representation "a"
00727 *
                      unless overridden by jCRPna.
00728 *
00729 *
                      Specifically the keywords are those listed above for
00730 *
                      WCSHDR_AUXIMG plus
00731 *
00732 #
                        WCSAXESa for WCAXna
00733 *
00734 *
                      which defines the coordinate dimensionality, and the following
00735 *
                      keywords that are parameterized by axis number:
00736 *
00737 #
                        CRPIXia
                                  for iCRPna
00738 #
                        PCi_ja
                                  for ijPCna
                        CDi_ja

00746 #
00747 #
                        PSi_ma
                                  for iSn_ma
00748 #
00749 #
                        CNAMEia
                                  for iCNAna
00750 #
                        CRDERia
                                  for iCRDna
00751 #
                        CSYERia
                                  for iCSYna
                        CZPHSia
00752 #
                                  for iCZPna
                                  for iCPRna
00753 #
                        CPERIia
00754 *
00755 *
                      where the image-header keywords on the left provide default
00756 *
                      values for the column specific keywords on the right.
00757 *
00758 *
                      This full inheritance mechanism only applies to binary table
00759 *
                      image arrays, not pixel lists, because in the latter case
00760 *
                      there is no well-defined association between coordinate axis
00761 *
                      number and column number (see note 9 below).
00762 *
00763 *
                      Note that CNAMEia, CRDERia, CSYERia, and their variants are
00764 *
                      not used by WCSLIB but are stored in the wcsprm struct as
00765 *
                      auxiliary information.
00766 *
                     Note especially that at least one wcsprm struct will be returned for each "a" found in one of the image header
00767 *
00768 *
00769 *
                      keywords listed above:
00770 *
00771 *
                      - If the image header keywords for "a" ARE NOT inherited by a
00772 *
                       binary table, then the struct will not be associated with
00773 *
                        any particular table column number and it is up to the user
00774 *
                        to provide an association.
00775 *
00776 *
                      - If the image header keywords for "a" ARE inherited by a
                        binary table image array, then those keywords are considered to be "exhausted" and do not result in a separate wcsprm
00777 *
00778 *
00779 *
                        struct.
00780 *
00781 *
             For example, to accept CD00i00j and PC00i00j and reject all other
00782 *
             extensions, use
00783 *
00784 =
               relax = WCSHDR_reject | WCSHDR_CD00i00j | WCSHDR_PC00i00j;
00785 *
00786 *
             The parser always treats EPOCH as subordinate to EQUINOXa if both are
00787 *
             present, and VSOURCEa is always subordinate to ZSOURCEa.
00788 *
00789 *
             Likewise, VELREF is subordinate to the formalism of WCS Paper III, see
00790 *
             spcaips().
00791 *
00792 *
             Neither wcspih() nor wcsbth() currently recognize the AIPS-convention
00793 *
             keywords ALTRPIX or ALTRVAL which effectively define an alternative
00794 *
             representation for a spectral axis.
00795 *
00796 *
          6: Depending on what flags have been set in its "relax" argument,
00797 *
             wcsbth() could return as many as 27027 wcsprm structs:
00798 *
00799 *
             - Up to 27 unattached representations derived from image header
00800 *
               keywords.
00801 *
00802 *
             - Up to 27 structs for each of up to 999 columns containing an image
00803 *
               arrays.
00804 *
00805 *
             - Up to 27 structs for a pixel list.
00806 *
00807 *
             Note that it is considered legitimate for a column to contain an image
00808 *
             array and also form part of a pixel list, and in particular that
00809 *
             wcsbth() does not check the TFORM keyword for a pixel list column to
00810 *
             check that it is scalar.
00811 *
00812 *
             In practice, of course, a realistic binary table header is unlikely to
```

```
contain more than a handful of images.
00814 *
00815 *
               In order for wcsbth() to create a wcsprm struct for a particular
00816 *
              coordinate representation, at least one WCS keyword that defines an \,
00817 *
               axis number must be present, either directly or by inheritance if
00818 *
              WCSHDR ALLIMG is set.
00820 *
               When the image header keywords for an alternate representation are
              inherited by a binary table image array via WCSHDR_ALLIMG, those keywords are considered to be "exhausted" and do not result in a
00821 *
00822 *
00823 *
               separate wcsprm struct. Otherwise they do.
00824 *
00825 *
           7: Neither wcspih() nor wcsbth() check for duplicated keywords, in most
00826 *
              cases they accept the last encountered.
00827 *
00828 *
           \$\colon \mathsf{wcspih}(\texttt{)} and \mathsf{wcsbth}(\texttt{)} use \mathsf{wcsnpv}(\texttt{)} and \mathsf{wcsnps}(\texttt{)} (refer to the prologue
              of wcs.h) to match the size of the pv[\ ] and ps[\ ] arrays in the wcsprm
00829 *
              structs to the number in the header. Consequently there are no unused elements in the pv[] and ps[] arrays, indeed they will often be of
00830 *
00831 *
00832 *
              zero length.
00833 *
00834 *
           9\colon \mbox{The FITS WCS} standard for pixel lists assumes that a pixel list
              defines one and only one image, i.e. that each row of the binary table refers to just one event, e.g. the detection of a single photon or neutrino, for which the device "pixel" coordinates are stored in
00835 *
00836 *
00837 *
00838 *
              separate scalar columns of the table.
00839 *
00840 *
               In the absence of a standard for pixel lists - or even an informal
00841 *
               description! - let alone a formal mechanism for identifying the columns
00842 *
               containing pixel coordinates (as opposed to pixel values or metadata
00843 *
               recorded at the time the photon or neutrino was detected), WCS Paper 1
00844 *
              discusses how the WCS keywords themselves may be used to identify them.
00845 *
00846 *
               In practice, however, pixel lists have been used to store multiple
00847 *
               images. Besides not specifying how to identify columns, the pixel list
00848 *
               convention is also silent on the method to be used to associate table
00849 *
               columns with image axes.
00851 *
               An additional shortcoming is the absence of a formal method for
00852 *
               associating global binary-table WCS keywords, such as WCSNna or MJDOBn,
00853 *
               with a pixel list image, whether one or several.
00854 *
              In light of these uncertainties, wcsbth() simply collects all WCS keywords for a particular pixel list coordinate representation (i.e.
00855 *
00856 *
               the "a" value in TCTYna) into one wcsprm struct. However, these
00857 *
00858 *
               alternates need not be associated with the same table columns and this
00859 *
               allows a pixel list to contain up to 27 separate images. As usual, if
00860 *
               one of these representations happened to contain more than two
00861 *
               celestial axes, for example, then an error would result when wcsset()
               is invoked on it. In this case the "colsel" argument could be used to
00862 *
00863 *
               restrict the columns used to construct the representation so that it
00864 *
               only contained one pair of celestial axes.
00865 *
              Global, binary-table WCS keywords are considered to apply to the pixel list image with matching alternate (e.g. the "a" value in LONPna or
00866 *
00867 *
              EQUIna), regardless of the table columns the image occupies. In other words, the column number is ignored (the "n" value in LONPna or
00868 *
00870 *
               EQUIna). This also applies for global, binary-table WCS keywords that
00871 *
               have no alternates, such as MJDOBn and OBSGXn, which match all images
00872 *
               in a pixel list. Take heed that this may lead to counterintuitive
00873 *
               behaviour, especially where such a keyword references a column that
00874 *
              does not store pixel coordinates, and moreso where the pixel list
              stores only a single image. In fact, as the column number, n, is ignored for such keywords, it would make no difference even if they
00875 *
00876 *
00877 *
               referenced non-existent columns. Moreover, there is no requirement for
00878 *
               consistency in the column numbers used for such keywords, even for
00879 *
              OBSGXn, OBSGYn, and OBSGZn which are meant to define the elements of a
00880 *
               coordinate vector. Although it would surely be perverse to construct a
              pixel list like this, such a situation may still arise in practice
00881 *
00882 *
               where columns are deleted from a binary table.
00883 *
00884 *
               The situation with global, binary-table WCS keywords becomes
00885 *
               potentially even more confusing when image arrays and pixel list images
00886 *
               coexist in one binary table. In that case, a keyword such as MJDOBn
00887 *
               may legitimately appear multiple times with n referencing different
               image arrays. Which then is the one that applies to the pixel list
00888 *
00889 *
               images? In this implementation, it is the last instance that appears
00890 *
               in the header, whether or not it is also associated with an image
00891 *
               array.
00892 *
00893 *
00894 * wcstab() - Tabular construction routine
00896 \star wcstab() assists in filling in the information in the wcsprm struct relating
00897 \star to coordinate lookup tables.
00898 *
00899 * Tabular coordinates ('TAB') present certain difficulties in that the main
```

```
00900 \star components of the lookup table - the multidimensional coordinate array plus
00901 \star an index vector for each dimension - are stored in a FITS binary table
00902 \star extension (BINTABLE). Information required to locate these arrays is stored
00903 \star in PVi_ma and PSi_ma keywords in the image header.
00904 *
00905 * wcstab() parses the PVi_ma and PSi_ma keywords associated with each 'TAB'
00906 \star axis and allocates memory in the wcsprm struct for the required number of
00907 \star tabprm structs. It sets as much of the tabprm struct as can be gleaned from
00908 \star the image header, and also sets up an array of wtbarr structs (described in
00909 \star the prologue of wtbarr.h) to assist in extracting the required arrays from
00910 * the BINTABLE extension(s).
00911 *
00912 * It is then up to the user to allocate memory for, and copy arrays from the
00913 * BINTABLE extension(s) into the tabprm structs. A CFITSIO routine,
00914 * fits_read_wcstab(), has been provided for this purpose, see getwcstab.h.
00915 \star wcsset() will automatically take control of this allocated memory, in 00916 \star particular causing it to be freed by wcsfree(); the user must not attempt
00917 * to free it after wcsset() has been called.
00919 \star Note that wcspih() and wcsbth() automatically invoke wcstab() on each of the
00920 * wcsprm structs that they return.
00921 *
00922 * Given and returned:
00923 *
          WCS
                     struct wcsprm*
00924 *
                                Coordinate transformation parameters (see below).
00925 *
00926 *
                                wcstab() sets ntab, tab, nwtb and wtb, allocating
00927 *
                                memory for the tab and wtb arrays. This allocated
00928 *
                                memory will be freed automatically by wcsfree().
00929 *
00930 * Function return value:
00931 *
                                Status return value:
                     int
00932 *
                                  0: Success.
00933 *
                                  1: Null wcsprm pointer passed.
00934 *
                                  2: Memory allocation failed.
                                  3: Invalid tabular parameters.
00935 *
00936 *
                                For returns > 1, a detailed error message is set in
                                wcsprm::err if enabled, see wcserr_enable().
00938
00939 *
00940 *
00941 * wcsidx() - Index alternate coordinate representations
00942 * --
00943 * wcsidx() returns an array of 27 indices for the alternate coordinate
00944 \star representations in the array of wcsprm structs returned by wcspih().
00945 \star the array returned by wcsbth() it returns indices for the unattached
00946 \star (colnum == 0) representations derived from image header keywords - use
00947 * wcsbdx() for those derived from binary table image arrays or pixel lists
00948 * keywords.
00949 *
00950 * Given:
00951 *
                                Number of coordinate representations in the array.
00952 *
00953 *
                     const struct wcsprm**
          WCS
00954 *
                                Pointer to an array of wcsprm structs returned by
00955 *
                                wcspih() or wcsbth().
00956 *
00957 * Returned:
00958 *
                     int[27] Index of each alternate coordinate representation in
          alts
                                the array: alts[0] for the primary, alts[1] for 'A', etc., set to -1 if not present.
00959 *
00960 *
00961 *
00962 *
                                For example, if there was no 'P' representation then
00963 *
00964 =
                                  alts['P'-'A'+1] == -1;
00965 *
00966 *
                                Otherwise, the address of its wcsprm struct would be
00967 *
00968 =
                                  wcs + alts['P'-'A'+1];
00970 * Function return value:
00971 *
                                Status return value:
                     int
00972 *
                                  0: Success.
00973 *
                                  1: Null wcsprm pointer passed.
00974 *
00975 *
00976 * wcsbdx() - Index alternate coordinate representions
00977 *
00978 \star wcsbdx() returns an array of 999 x 27 indices for the alternate coordinate
00979 * representions for binary table image arrays xor pixel lists in the array of 00980 * wcsprm structs returned by wcsbth(). Use wcsidx() for the unattached
00981 * representations derived from image header keywords.
00982 *
00983 * Given:
00984 *
          nwcs
                    int
                               Number of coordinate representations in the array.
00985 *
00986 *
                    const struct wcsprm**
          WCS
```

```
00987 *
                                  Pointer to an array of wcsprm structs returned by
00988 *
00989 *
00990 *
          type
                      int
                                 Select the type of coordinate representation:
00991 *
                                   0: binary table image arrays,
1: pixel lists.
00992 *
00993 *
00994 * Returned:
00995 *
                      short[1000][28]
          alts
00996 *
                                  Index of each alternate coordinate represention in the
                                  array: alts[col][0] for the primary, alts[col][1] for 'A', to alts[col][26] for 'Z', where col is the
00997 *
00998 *
                                 1-relative column number, and col == 0 is used for unattached image headers. Set to -1 if not present.
00999 *
01000 *
01001 *
                                  alts[col][27] counts the number of coordinate
01002 *
01003 *
                                  representations of the chosen type for each column.
01004 *
01005 *
                                 For example, if there was no 'P' represention for
01006
                                 column 13 then
01007 *
01008 =
                                    alts[13]['P'-'A'+1] == -1;
01009 *
01010 *
                                 Otherwise, the address of its wcsprm struct would be
01011 *
01012 =
                                    wcs + alts[13]['P'-'A'+1];
01013
01014 * Function return value:
01015 *
                      int
                                 Status return value:
01016 *
                                    0: Success.
01017
                                    1: Null wcsprm pointer passed.
01018 *
01019 *
01020 \star wcsvfree() - Free the array of wcsprm structs
01021 *
01022 \star wcsvfree() frees the memory allocated by wcspih() or wcsbth() for the array
01023 \star of wcsprm structs, first invoking wcsfree() on each of the array members.
01025 * Given and returned:
01026 * nwcs
                                 Number of coordinate representations found; set to 0
01027 *
                                  on return.
01028 *
01029 *
          WCS
                      struct wcsprm**
01030 *
                                 Pointer to the array of wcsprm structs; set to 0x0 on
01031 *
                                 return.
01032 *
01033 * Function return value:
                      int
01034 *
                                 Status return value:
01035 *
                                    0: Success.
01036 *
                                    1: Null wcsprm pointer passed.
01037
01038 *
01039 \star wcshdo() - Write out a wcsprm struct as a FITS header
01040 *
01041 * wcshdo() translates a wcsprm struct into a FITS header. If the colnum
01042 \star member of the struct is non-zero then a binary table image array header will 01043 \star be produced. Otherwise, if the colax[] member of the struct is set non-zero
01044 \star then a pixel list header will be produced. Otherwise, a primary image or
01045 * image extension header will be produced.
01046 *
01047 \star If the struct was originally constructed from a header, e.g. by wcspih(),
01048 \star the output header will almost certainly differ in a number of respects:
01049 *
01050 *
             The output header only contains WCS-related keywords. In particular, it
01051 *
             does not contain syntactically-required keywords such as SIMPLE, NAXIS,
01052 *
             BITPIX, or END.
01053 *
           - Elements of the PCi_ja matrix will be written if and only if they differ from the unit matrix. Thus, if the matrix is unity then no elements
01054 *
01055 *
01056 *
             will be written.
01057 *
01058 *
           - The redundant keywords MJDREF, JDREF, JDREFI, JDREFF, all of which
             duplicate MJDREFI + MJDREFF, are never written. OBSGEO-[LBH] are not written if OBSGEO-[XYZ] are defined.
01059 *
01060 *
01061 *
           - Deprecated (e.g. CROTAn, RESTFREQ, VELREF, RADECSYS, EPOCH, VSOURCEa) or
01062 *
01063 *
             non-standard usage will be translated to standard (this is partially
01064 *
             dependent on whether wcsfix() was applied).
01065 *
01066 *
           - Additional keywords such as WCSAXESa, CUNITia, LONPOLEa and LATPOLEa may
01067 *
             appear.
01068 *
01069 *
           - Quantities will be converted to the units used internally, basically SI
01070 *
             with the addition of degrees.
01071 *
01072 *
           - Floating-point quantities may be given to a different decimal precision.
01073 *
```

```
- The original keycomments will be lost, although wcshdo() tries hard to
01075 *
            write meaningful comments.
01076 *
01077 *
          - Keyword order will almost certainly be changed.
01078 *
01079 * Keywords can be translated between the image array, binary table, and pixel
01080 \star lists forms by manipulating the colnum or colax[] members of the wcsprm
01081 * struct.
01082 *
01083 * Given:
01084 *
                               Vector of flag bits that controls the degree of
          ctrl
                    int
                               permissiveness in departing from the published WCS
01085 *
01086 *
                                standard, and also controls the formatting of
                                floating-point keyvalues. Set it to zero to get the
01087 *
01088 *
                               default behaviour.
01089 *
                               Flag bits for the degree of permissiveness:
01090 *
01091 *
                                 WCSHDO_none: Recognize only FITS keywords defined by
                                     the published WCS standard.
01092 *
01093 *
                                 WCSHDO_all: Admit all recognized informal extensions
01094 *
                                     of the WCS standard.
01095 *
                               Fine-grained control of the degree of permissiveness
01096 *
                               is also possible as explained in the notes below.
01097 *
01098 *
                               As for controlling floating-point formatting, by
                               default wcshdo() uses "%20.12G" for non-parameterized
01099 *
01100 *
                                keywords such as LONPOLEa, and attempts to make the
01101 *
                                header more human-readable by using the same "%f"
01102 *
                                format for all values of each of the following
01103 *
                                parameterized keywords: CRPIXja, PCi_ja, and CDELTia
01104 *
                                (n.b. excluding CRVALia). Each has the same field
01105 *
                                width and precision so that the decimal points line
01106 *
                                    The precision, allowing for up to 15 significant
                                digits, is chosen so that there are no excess trailing
01107 *
                               zeroes. A similar formatting scheme applies by default for distortion function parameters.
01108 *
01109 *
01110 *
01111 *
                                However, where the values of, for example, CDELTia
01112 *
                                differ by many orders of magnitude, the default
                                formatting scheme may cause unacceptable loss of
01113 *
01114 *
                                precision for the lower-valued keyvalues. Thus the
01115 *
                               default behaviour may be overridden:
                                 WCSHDO P12: Use "%20.12G" format for all floating-
01116 *
                                     point keyvalues (12 significant digits).
01117 *
                                 WCSHDO_P13: Use "%21.13G" format for all floating-
01118 *
01119 *
                                     point keyvalues (13 significant digits)
01120 *
                                 WCSHDO_P14: Use "%22.14G" format for all floating-
                                 point keyvalues (14 significant digits). WCSHDO_P15: Use "%23.15G" format for all floating-
01121 *
01122 *
01123 *
                                     point keyvalues (15 significant digits).
                                 WCSHDO_P16: Use "%24.16G" format for all floating-
01124 *
01125 *
                                     point keyvalues (16 significant digits).
01126 *
                                 WCSHDO_P17: Use "%25.17G" format for all floating-
01127 *
                                     point keyvalues (17 significant digits).
01128 *
                                If more than one of the above flags are set, the
                               highest number of significant digits prevails. In
01129 *
                               addition, there is an anciliary flag:
01130 *
01131 *
                                 WCSHDO_EFMT: Use "%E" format instead of the default
01132 *
                                     "%G" format above.
                               Note that excess trailing zeroes are stripped off the fractional part with "%G" (which never occurs with
01133 *
01134 *
                                "%E"). Note also that the higher-precision options
01135 *
01136 *
                                eat into the keycomment area. In this regard,
                                WCSHDO_P14 causes minimal disruption with "%G" format,
01137 *
01138 *
                               while WCSHDO_P13 is appropriate with "%E".
01139 *
01140 * Given and returned:
01141 *
          WCS
                    struct wcsprm*
                               Pointer to a wcsprm struct containing coordinate
01142 *
01143 *
                               transformation parameters. Will be initialized if
01144 *
01145 *
01146 * Returned:
                               Number of FITS header keyrecords returned in the
01147 *
         nkeyrec
                    int*
01148 *
                                "header" array.
01149 *
01150 *
          header
                    char**
                               Pointer to an array of char holding the header.
01151 *
                               Storage for the array is allocated by wcshdo() in
                               blocks of 2880 bytes (32 x 80-character keyrecords)
01152 *
01153 *
                               and must be freed by the user to avoid memory leaks.
01154 *
                               See wcsdealloc().
01155 *
                                Each keyrecord is 80 characters long and is *NOT*
01156
01157 *
                                null-terminated, so the first keyrecord starts at
01158 *
                                (*header)[0], the second at (*header)[80], etc.
01159
01160 * Function return value:
```

```
int
                               Status return value (associated with wcs_errmsq[]):
01162 *
                                 0: Success.
01163 *
                                 1: Null wcsprm pointer passed.
01164 *
                                 2: Memory allocation failed.
01165 *
                                 3: Linear transformation matrix is singular.
01166 *
                                 4: Inconsistent or unrecognized coordinate axis
01167
                                    types.
01168 *
                                 5: Invalid parameter value.
01169 *
                                 6: Invalid coordinate transformation parameters.
01170 *
                                 7: Ill-conditioned coordinate transformation
01171 *
                                    parameters.
01172 *
01173 *
                               For returns > 1, a detailed error message is set in
01174 *
                               wcsprm::err if enabled, see wcserr_enable().
01175 *
01176 * Notes:
         1: wcshdo() interprets the "relax" argument as a vector of flag bits to
01177 *
             provide fine-grained control over what non-standard WCS keywords to write. The flag bits are subject to change in future and should be set
01178 *
01179 *
01180 *
             by using the preprocessor macros (see below) for the purpose.
01181 *
01182 *
             - WCSHDO_none: Don't use any extensions.
01183 *
01184 *
             - WCSHDO all: Write all recognized extensions, equivalent to setting
01185 *
                     each flag bit.
01186 *
01187 *
             - WCSHDO_safe: Write all extensions that are considered to be safe and
01188 *
01189 *
01190 *
             - WCSHDO_DOBSn: Write DOBSn, the column-specific analogue of DATE-OBS
01191 *
                     for use in binary tables and pixel lists. WCS Paper III
01192 *
                      introduced DATE-AVG and DAVGn but by an oversight DOBSn (the
01193 *
                      obvious analogy) was never formally defined by the standard.
01194 *
                      The alternative to using DOBSn is to write DATE-OBS which
01195 *
                      applies to the whole table. This usage is considered to be
01196 *
                     safe and is recommended.
01197 *
01198 *
             - WCSHDO_TPCn_ka: WCS Paper I defined
01199 *
01200 *
                     - TPn_ka and TCn_ka for pixel lists
01201 *
01202 *
                     but WCS Paper II uses TPCn_ka in one example and subsequently
                     the errata for the WCS papers legitimized the use of
01203 *
01204 *
01205 *
                     - TPCn_ka and TCDn_ka for pixel lists
01206 *
01207 *
                     provided that the keyword does not exceed eight characters.
01208 *
                      This usage is considered to be safe and is recommended because
01209 *
                     of the non-mnemonic terseness of the shorter forms.
01210 *
01211 *
             - WCSHDO_PVn_ma: WCS Paper I defined
01212 *
01213 *
                     - iVn_ma and iSn_ma for bintables and
01214 *
                     - TVn_ma and TSn_ma for pixel lists
01215 *
01216 *
                     but WCS Paper II uses iPVn ma and TPVn ma in the examples and
                     subsequently the errata for the WCS papers legitimized the use
01217 *
01218 *
01219 *
01220 *
                     - iPVn_ma and iPSn_ma for bintables and
01221 *
                     - TPVn_ma and TPSn_ma for pixel lists
01222 *
01223 *
                     provided that the keyword does not exceed eight characters.
                     This usage is considered to be safe and is recommended because
01224 *
01225 *
                     of the non-mnemonic terseness of the shorter forms.
01226 *
01227 *
             - WCSHDO_CRPXna: For historical reasons WCS Paper I defined
01228 *
01229 *
                      - jCRPXn, iCDLTn, iCUNIn, iCTYPn, and iCRVLn for bintables and
01230 *
                      - TCRPXn, TCDLTn, TCUNIn, TCTYPn, and TCRVLn for pixel lists
01231 *
01232 *
                     for use without an alternate version specifier. However,
01233 *
                     because of the eight-character keyword constraint, in order to
01234 *
                     accommodate column numbers greater than 99 WCS Paper I also
01235 *
                     defined
01236 *
01237 *
                       jCRPna, iCDEna, iCUNna, iCTYna and iCRVna for bintables and
01238 *
                     - TCRPna, TCDEna, TCUNna, TCTYna and TCRVna for pixel lists
01239 *
01240 *
                     for use with an alternate version specifier (the "a"). Like
01241 *
                     the PC, CD, PV, and PS keywords there is an obvious tendency to
01242 *
                     confuse these two forms for column numbers up to 99.
01243 *
                      very unlikely that any parser would reject keywords in the
01244 *
                      first set with a non-blank alternate version specifier so this
01245 *
                     usage is considered to be safe and is recommended.
01246 *
01247 *
             - WCSHDO CNAMna: WCS Papers I and III defined
```

```
01248 *
                     - iCNAna, iCRDna, and iCSYna for bintables and - TCNAna, TCRDna, and TCSYna for pixel lists
01249 *
01250 *
01251 *
01252 *
                    By analogy with the above, the long forms would be
01253 *
                     - iCNAMna, iCRDEna, and iCSYEna for bintables and
                     - TCNAMna, TCRDEna, and TCSYEna for pixel lists
01255 *
01256 *
01257 *
                     Note that these keywords provide auxiliary information only,
01258 *
                     none of them are needed to compute world coordinates. This
01259 *
                     usage is potentially unsafe and is not recommended at this
01260 *
                     time.
01261 *
01262 *
             - WCSHDO_WCSNna: In light of wcsbth() note 4, write WCSNna instead of
01263 *
                     {\tt TWCSna} for pixel lists. While {\tt wcsbth}(\tt) treats {\tt WCSNna} and
                     TWCSna as equivalent, other parsers may not. Consequently,
01264 *
01265 *
                     this usage is potentially unsafe and is not recommended at this
01266 *
                     time.
01267 *
01268 *
01269 \star Global variable: const char \starwcshdr_errmsg[] - Status return messages
01270 * -----
01271 * Error messages to match the status value returned from each function.
01272 * Use wcs_errmsq[] for status returns from wcshdo().

6.33 wcsprintf.h File Reference

```
#include <inttypes.h>
#include <stdio.h>
```

Macros

#define WCSPRINTF_PTR(str1, ptr, str2)
 Print addresses in a consistent way.

Functions

- int wcsprintf set (FILE *wcsout)
 - Set output disposition for wcsprintf() and wcsfprintf().
- int wcsprintf (const char *format,...)

Print function used by WCSLIB diagnostic routines.

• int wcsfprintf (FILE *stream, const char *format,...)

Print function used by WCSLIB diagnostic routines.

const char * wcsprintf_buf (void)

Get the address of the internal string buffer.

6.33.1 Detailed Description

Routines in this suite allow diagnostic output from celprt(), linprt(), prjprt(), spcprt(), tabprt(), wcsprt(), and wcserr_prt() to be redirected to a file or captured in a string buffer. Those routines all use wcsprintf() for output. Likewise wcsfprintf() is used by wcsbth() and wcspih(). Both functions may be used by application programmers to have other output go to the same place.

6.33.2 Macro Definition Documentation

WCSPRINTF PTR

Print addresses in a consistent way.

WCSPRINTF PTR() is a preprocessor macro used to print addresses in a consistent way.

On some systems the "p" format descriptor renders a NULL pointer as the string "0x0". On others, however, it produces "0" or even "(nil)". On some systems a non-zero address is prefixed with "0x", on others, not.

The **WCSPRINTF_PTR**() macro ensures that a NULL pointer is always rendered as "0x0" and that non-zero addresses are prefixed with "0x" thus providing consistency, for example, for comparing the output of test programs.

6.33.3 Function Documentation

wcsprintf_set()

Set output disposition for wcsprintf() and wcsfprintf().

wcsprintf_set() sets the output disposition for wcsprintf() which is used by the celprt(), linprt(), prjprt(), spcprt(), tabprt(), wcsprt(), and wcsprr prt() routines, and for wcsfprintf() which is used by wcsbth() and wcspih().

Parameters

in	wcsout	Pointer to an output stream that has been opened for writing, e.g. by the fopen() stdio library
		function, or one of the predefined stdio output streams - stdout and stderr. If zero (NULL),
		output is written to an internally-allocated string buffer, the address of which may be obtained
		by wcsprintf_buf().

Returns

Status return value:

• 0: Success.

wcsprintf()

Print function used by WCSLIB diagnostic routines.

wcsprintf() is used by celprt(), linprt(), prjprt(), spcprt(), tabprt(), wcsprt(), and wcserr_prt() for diagnostic output which by default goes to stdout. However, it may be redirected to a file or string buffer via wcsprintf_set().

Parameters

in	format	Format string, passed to one of the printf(3) family of stdio library functions.
in		Argument list matching format, as per printf(3).

Returns

Number of bytes written.

wcsfprintf()

Print function used by WCSLIB diagnostic routines.

wcsfprintf() is used by wcsbth(), and wcspih() for diagnostic output which they send to stderr. However, it may be redirected to a file or string buffer via wcsprintf_set().

Parameters

in	stream	The output stream if not overridden by a call to wcsprintf_set().
in	format	Format string, passed to one of the printf(3) family of stdio library functions.
in		Argument list matching format, as per printf(3).

Returns

Number of bytes written.

wcsprintf_buf()

Get the address of the internal string buffer.

wcsprintf_buf() returns the address of the internal string buffer created when wcsprintf_set() is invoked with its FILE* argument set to zero.

Returns

Address of the internal string buffer. The user may free this buffer by calling wcsprintf_set() with a valid FILE*, e.g. stdout. The free() stdlib library function must NOT be invoked on this const pointer.

00024 *
00025 \star WCSLIB 8.3 - C routines that implement the FITS World Coordinate System
00026 \star (WCS) standard. Refer to the README file provided with WCSLIB for an
00027 * overview of the library.
00028 *
00029 *
00030 * Summary of the wcsprintf routines
00031 *
00032 \star Routines in this suite allow diagnostic output from celprt(), linprt(),
00033 \star prjprt(), spcprt(), tabprt(), wcsprt(), and wcserr_prt() to be redirected to 00034 \star a file or captured in a string buffer. Those routines all use wcsprintf()
00035 * for output.
                      Likewise wcsfprintf() is used by wcsbth() and wcspih().
00036 \star functions may be used by application programmers to have other output go to
00037 \star the same place.
00038 *
00039 *
00040 * wcsprintf() - Print function used by WCSLIB diagnostic routines
00041 * -
00042 * wcsprintf() is used by celprt(), linprt(), prjprt(), spcprt(), tabprt(),
00043 \star wcsprt(), and wcserr_prt() for diagnostic output which by default goes to
00044 * stdout.
                  However, it may be redirected to a file or string buffer via
00045 * wcsprintf_set().
00046 *
00047 * Given:
00048 * format char*
                                Format string, passed to one of the printf(3) family
00049 *
                                of stdio library functions.
```

```
00050 *
00051 *
                    mixed
                               Argument list matching format, as per printf(3).
00052 *
00053 * Function return value:
00054 *
                    int.
                               Number of bytes written.
00055 *
00057 \star wcsfprintf() - Print function used by WCSLIB diagnostic routines
00058 *
00059 \star wcsfprintf() is used by wcsbth(), and wcspih() for diagnostic output which
00060 \star they send to stderr. However, it may be redirected to a file or string
00061 * buffer via wcsprintf_set().
00062 *
00063 * Given:
00064 * stream
                   FILE*
                               The output stream if not overridden by a call to
00065 *
                               wcsprintf_set().
00066 *
00067 *
         format char*
                               Format string, passed to one of the printf(3) family
00068 *
                               of stdio library functions.
00069 *
00070 *
         . . .
                  mixed
                               Argument list matching format, as per printf(3).
00071 *
00072 * Function return value:
00073 *
                    int.
                               Number of bytes written.
00074 *
00075 *
00076 * wcsprintf_set() - Set output disposition for wcsprintf() and wcsfprintf()
00077 *
00078 \star wcsprintf_set() sets the output disposition for wcsprintf() which is used by
00079 * the celprt(), linprt(), prjprt(), spcprt(), tabprt(), wcsprt(), and 00080 * wcserr_prt() routines, and for wcsfprintf() which is used by wcsbth() and
00081 * wcspih().
00082 *
00083 * Given:
          wcsout
00084 *
                   FILE*
                               Pointer to an output stream that has been opened for
00085 *
                               writing, e.g. by the fopen() stdio library function,
00086 *
                               or one of the predefined stdio output streams - stdout
                               and stderr. If zero (NULL), output is written to an
00087 *
00088 *
                                internally-allocated string buffer, the address of
00089 *
                                which may be obtained by wcsprintf_buf().
00090 *
00091 * Function return value:
00092 *
                               Status return value:
                    int
00093 *
                                 0: Success.
00094 *
00095 *
00096 \star wcsprintf_buf() - Get the address of the internal string buffer
00097 * --
00098 * wcsprintf buf() returns the address of the internal string buffer created
00099 * when wcsprintf_set() is invoked with its FILE* argument set to zero.
00100 *
00101 * Function return value:
00102 *
                    const char *
00103 *
                                Address of the internal string buffer. The user may
                                free this buffer by calling wcsprintf_set() with a valid FILE*, e.g. stdout. The free() stdlib library
00104 *
00105 *
                                function must NOT be invoked on this const pointer.
00106
00107 *
00108 *
00109 * WCSPRINTF_PTR() macro - Print addresses in a consistent way
00110 *
00111 * WCSPRINTF_PTR() is a preprocessor macro used to print addresses in a
00112 * consistent way.
00113 >
00114 \star On some systems the "%p" format descriptor renders a NULL pointer as the
00115 \star string "0x0". On others, however, it produces "0" or even "(nil)". On
00116 \star some systems a non-zero address is prefixed with "0x", on others, not.
00117 *
00118 * The WCSPRINTF_PTR() macro ensures that a NULL pointer is always rendered as
00119 * "0x0" and that non-zero addresses are prefixed with "0x" thus providing
00120 \star consistency, for example, for comparing the output of test programs.
00121 *
00122 *===

Macros

• #define WCSTRIG TOL 1e-10

Domain tolerance for asin() and acos() functions.

Functions

• double cosd (double angle)

Cosine of an angle in degrees.

double sind (double angle)

Sine of an angle in degrees.

void sincosd (double angle, double *sin, double *cos)

Sine and cosine of an angle in degrees.

• double tand (double angle)

Tangent of an angle in degrees.

• double acosd (double x)

Inverse cosine, returning angle in degrees.

• double asind (double y)

Inverse sine, returning angle in degrees.

• double atand (double s)

Inverse tangent, returning angle in degrees.

• double atan2d (double y, double x)

Polar angle of (x, y), in degrees.

6.35.1 Detailed Description

When dealing with celestial coordinate systems and spherical projections (some moreso than others) it is often desirable to use an angular measure that provides an exact representation of the latitude of the north or south pole. The WCSLIB routines use the following trigonometric functions that take or return angles in degrees:

- cosd()
- sind()

- tand()
- acosd()
- asind()
- atand()
- atan2d()
- sincosd()

These "trigd" routines are expected to handle angles that are a multiple of 90° returning an exact result. Some C implementations provide these as part of a system library and in such cases it may (or may not!) be preferable to use them. WCSLIB provides wrappers on the standard trig functions based on radian measure, adding tests for multiples of 90° .

However, wcstrig.h also provides the choice of using preprocessor macro implementations of the trigd functions that don't test for multiples of 90° (compile with -DWCSTRIG_MACRO). These are typically 20% faster but may lead to problems near the poles.

6.35.2 Macro Definition Documentation

WCSTRIG_TOL

```
#define WCSTRIG_TOL 1e-10
```

Domain tolerance for asin() and acos() functions.

Domain tolerance for the asin() and acos() functions to allow for floating point rounding errors.

If v lies in the range $1 < |v| < 1 + WCSTRIG_TOL$ then it will be treated as |v| == 1.

6.35.3 Function Documentation

cosd()

```
double cosd ( double angle )
```

Cosine of an angle in degrees.

cosd() returns the cosine of an angle given in degrees.

Parameters

```
in angle [deg].
```

Returns

Cosine of the angle.

sind()

```
double sind ( \mbox{double $\it angle$} \ )
```

Sine of an angle in degrees.

sind() returns the sine of an angle given in degrees.

Parameters

in	angle	[deg].

Returns

Sine of the angle.

sincosd()

Sine and cosine of an angle in degrees.

sincosd() returns the sine and cosine of an angle given in degrees.

Parameters

in	angle	[deg].
out	sin	Sine of the angle.
out	cos	Cosine of the angle.

Returns

tand()

```
double tand ( \mbox{double $\it angle$} \ )
```

Tangent of an angle in degrees.

 ${f tand}()$ returns the tangent of an angle given in degrees.

Parameters

in a	ngle	[deg].
------	------	--------

Returns

Tangent of the angle.

acosd()

```
double acosd ( \label{eq:double x } \mbox{double } x \mbox{ )}
```

Inverse cosine, returning angle in degrees.

 $\boldsymbol{acosd}()$ returns the inverse cosine in degrees.

Parameters

```
in x in the range [-1,1].
```

Returns

Inverse cosine of x [deg].

asind()

```
double asind ( \mbox{double } y \mbox{ )}
```

Inverse sine, returning angle in degrees.

asind() returns the inverse sine in degrees.

Parameters

```
in y in the range [-1,1].
```

Returns

Inverse sine of y [deg].

atand()

```
double at and ( \mbox{double } s \mbox{ )}
```

INVERSE	tangent	returning	andie	ın	dedrees
111110130	tarigorit,	returning	angio		acgrees.

atand() returns the inverse tangent in degrees.

6.36 wcstrig.h 441

Parameters

|--|

Returns

Inverse tangent of s [deg].

atan2d()

```
double atan2d ( \label{eq:double y, double x, double x}
```

Polar angle of (x, y), in degrees.

atan2d() returns the polar angle, β , in degrees, of polar coordinates (ρ, β) corresponding to Cartesian coordinates (x, y). It is equivalent to the $\arg(x, y)$ function of WCS Paper II, though with transposed arguments.

Parameters

in	У	Cartesian y -coordinate.
in	Х	Cartesian x -coordinate.

Returns

Polar angle of (x, y) [deg].

6.37.1 Detailed Description

Routines in this suite deal with units specifications and conversions, as described in

```
"Representations of world coordinates in FITS",
Greisen, E.W., & Calabretta, M.R. 2002, A&A, 395, 1061 (WCS Paper I)
```

The Flexible Image Transport System (FITS), a data format widely used in astronomy for data interchange and archive, is described in

```
"Definition of the Flexible Image Transport System (FITS), version 3.0", Pence, W.D., Chiappetti, L., Page, C.G., Shaw, R.A., & Stobie, E. 2010, A&A, 524, A42 - http://dx.doi.org/10.1051/0004-6361/201015362
```

See also http:

These routines perform basic units-related operations:

- wcsunitse(): given two unit specifications, derive the conversion from one to the other.
- wcsutrne(): translates certain commonly used but non-standard unit strings. It is intended to be called before wcsulexe() which only handles standard FITS units specifications.
- wcsulexe(): parses a standard FITS units specification of arbitrary complexity, deriving the conversion to canonical units.

6.37.2 Macro Definition Documentation

WCSUNITS_PLANE_ANGLE

```
#define WCSUNITS_PLANE_ANGLE 0
```

Array index for plane angle units type.

Array index for plane angle units in the *units* array returned by wcsulex(), and the wcsunits_types[] and wcsunits_units[] global variables.

WCSUNITS_SOLID_ANGLE

```
#define WCSUNITS_SOLID_ANGLE 1
```

Array index for solid angle units type.

Array index for solid angle units in the *units* array returned by wcsulex(), and the wcsunits_types[] and wcsunits_units[] global variables.

WCSUNITS_CHARGE

```
#define WCSUNITS_CHARGE 2
```

Array index for charge units type.

Array index for charge units in the *units* array returned by wcsulex(), and the wcsunits_types[] and wcsunits_units[] global variables.

WCSUNITS MOLE

```
#define WCSUNITS_MOLE 3
```

Array index for mole units type.

Array index for mole ("gram molecular weight") units in the *units* array returned by wcsulex(), and the wcsunits_types[] and wcsunits_units[] global variables.

WCSUNITS_TEMPERATURE

```
#define WCSUNITS_TEMPERATURE 4
```

Array index for temperature units type.

Array index for temperature units in the *units* array returned by wcsulex(), and the wcsunits_types[] and wcsunits_units[] global variables.

WCSUNITS_LUMINTEN

```
#define WCSUNITS_LUMINTEN 5
```

Array index for luminous intensity units type.

Array index for luminous intensity units in the *units* array returned by wcsulex(), and the wcsunits_types[] and wcsunits units[] global variables.

WCSUNITS MASS

```
#define WCSUNITS_MASS 6
```

Array index for mass units type.

Array index for mass units in the *units* array returned by wcsulex(), and the wcsunits_types[] and wcsunits_units[] global variables.

WCSUNITS_LENGTH

```
#define WCSUNITS_LENGTH 7
```

Array index for length units type.

Array index for length units in the *units* array returned by wcsulex(), and the wcsunits_types[] and wcsunits_units[] global variables.

WCSUNITS_TIME

```
#define WCSUNITS_TIME 8
```

Array index for time units type.

Array index for time units in the *units* array returned by wcsulex(), and the wcsunits_types[] and wcsunits_units[] global variables.

WCSUNITS_BEAM

```
#define WCSUNITS_BEAM 9
```

Array index for beam units type.

Array index for beam units in the *units* array returned by wcsulex(), and the wcsunits_types[] and wcsunits_units[] global variables.

WCSUNITS_BIN

```
#define WCSUNITS_BIN 10
```

Array index for bin units type.

Array index for bin units in the *units* array returned by wcsulex(), and the wcsunits_types[] and wcsunits_units[] global variables.

WCSUNITS_BIT

```
#define WCSUNITS_BIT 11
```

Array index for bit units type.

Array index for bit units in the *units* array returned by wcsulex(), and the wcsunits_types[] and wcsunits_units[] global variables.

WCSUNITS COUNT

```
#define WCSUNITS_COUNT 12
```

Array index for count units type.

Array index for count units in the *units* array returned by wcsulex(), and the wcsunits_types[] and wcsunits_units[] global variables.

WCSUNITS_MAGNITUDE

```
#define WCSUNITS_MAGNITUDE 13
```

Array index for stellar magnitude units type.

Array index for stellar magnitude units in the *units* array returned by wcsulex(), and the wcsunits_types[] and wcsunits units[] global variables.

WCSUNITS_PIXEL

```
#define WCSUNITS_PIXEL 14
```

Array index for pixel units type.

Array index for pixel units in the *units* array returned by wcsulex(), and the wcsunits_types[] and wcsunits_units[] global variables.

WCSUNITS_SOLRATIO

```
#define WCSUNITS_SOLRATIO 15
```

Array index for solar mass ratio units type.

Array index for solar mass ratio units in the *units* array returned by wcsulex(), and the wcsunits_types[] and wcsunits_units[] global variables.

WCSUNITS_VOXEL

```
#define WCSUNITS_VOXEL 16
```

Array index for voxel units type.

Array index for voxel units in the *units* array returned by wcsulex(), and the wcsunits_types[] and wcsunits_units[] global variables.

WCSUNITS_NTYPE

```
#define WCSUNITS_NTYPE 17
```

Number of entries in the units array.

Number of entries in the *units* array returned by wcsulex(), and the wcsunits_types[] and wcsunits_units[] global variables.

6.37.4 Function Documentation

wcsunitse()

FITS units specification conversion.

wcsunitse() derives the conversion from one system of units to another.

A deprecated form of this function, wcsunits(), lacks the wcserr** parameter.

Parameters

in	have	FITS units specification to convert from (null- terminated), with or without surrounding square brackets (for inline specifications); text following the closing bracket is ignored.
in	want	FITS units specification to convert to (null- terminated), with or without surrounding square brackets (for inline specifications); text following the closing bracket is ignored.
out	scale,offset,power	Convert units using pow(scale*value + offset, power); Normally offset is zero except for log() or ln() conversions, e.g. "log(MHz)" to "ln(Hz)". Likewise, power is normally unity except for exp() conversions, e.g. "exp(ms)" to "exp(/Hz)". Thus conversions ordinarily consist of value *= scale;
out	err	If enabled, for function return values > 1, this struct will contain a detailed error message, see wcserr_enable(). May be NULL if an error message is not desired. Otherwise, the user is responsible for deleting the memory allocated for the wcserr struct.

Returns

Status return value:

- 0: Success.
- 1-9: Status return from wcsulexe().
- 10: Non-conformant unit specifications.
- 11: Non-conformant functions.

scale is zeroed on return if an error occurs.

wcsutrne()

```
int wcsutrne (
    int ctrl,
    char unitstr[],
    struct wcserr ** err )
```

Translation of non-standard unit specifications.

wcsutrne() translates certain commonly used but non-standard unit strings, e.g. "DEG", "MHZ", "KELVIN", that are not recognized by wcsulexe(), refer to the notes below for a full list. Compounds are also recognized, e.g. "JY/BEAM" and "KM/SEC/SEC". Extraneous embedded blanks are removed.

A deprecated form of this function, wcsutrn(), lacks the wcserr** parameter.

Parameters

in	ctrl	Although "S" is commonly used to represent seconds, its translation to "s" is potentially unsafe since the standard recognizes "S" formally as Siemens, however rarely that may be used. The same applies to "H" for hours (Henry), and "D" for days (Debye). This bit-flag controls what to do in such cases:
		1: Translate "S" to "s".2: Translate "H" to "h".
		• 4: Translate "D" to "d".
		Thus ctrl == 0 doesn't do any unsafe translations, whereas ctrl == 7 does all of them.
in, out	unitstr	Null-terminated character array containing the units specification to be translated. Inline units specifications in a FITS header keycomment are also handled. If the first non-blank character in unitstr is '[' then the unit string is delimited by its matching ']'. Blanks preceding '[' will be stripped off, but text following the closing bracket will be preserved without modification.
in,out	err	If enabled, for function return values > 1, this struct will contain a detailed error message, see wcserr_enable(). May be NULL if an error message is not desired. Otherwise, the user is responsible for deleting the memory allocated for the wcserr struct.

Returns

Status return value:

- -1: No change was made, other than stripping blanks (not an error).
- 0: Success.
- 9: Internal parser error.
- 12: Potentially unsafe translation, whether applied or not (see notes).

Notes:

Translation of non-standard unit specifications: apart from leading and trailing blanks, a case-sensitive match
is required for the aliases listed below, in particular the only recognized aliases with metric prefixes are "KM",
"KHZ", "MHZ", and "GHZ". Potentially unsafe translations of "D", "H", and "S", shown in parentheses, are
optional.

```
Unit
           Recognized aliases
Angstrom
           Angstroms angstrom angstroms
           arcmins, ARCMIN, ARCMINS
arcmin
           arcsecs, ARCSEC, ARCSECS
arcsec
beam
           BEAM
byte
           Byte
           day, days, (D), DAY, DAYS
           degree, degrees, Deg, Degree, Degrees, DEG, DEGREE, DEGREES
deg
GHz
           GHZ
           hr, (H), HR
Ηz
           hz, HZ
kHz
           KHZ
Jу
           JΥ
           kelvin, kelvins, Kelvin, Kelvins, KELVIN, KELVINS
km
           metre, meter, metres, meters, M, METRE, METER, METRES,
m
           METERS
min
           MIN
MHz.
           MHZ.
Ohm
           ohm
           pascal, pascals, Pascal, Pascals, PASCAL, PASCALS
Ра
pixel
           pixels, PIXEL, PIXELS
```

```
rad radian, radians, RAD, RADIAN, RADIANS s sec, second, seconds, (S), SEC, SECOND, SECONDS V volt, volts, Volt, Volts, VOLT, VOLTS yr year, years, YR, YEAR, YEARS
```

The aliases "angstrom", "ohm", and "Byte" for (Angstrom, Ohm, and byte) are recognized by wcsulexe() itself as an unofficial extension of the standard, but they are converted to the standard form here.

wcsulexe()

FITS units specification parser.

wcsulexe() parses a standard FITS units specification of arbitrary complexity, deriving the scale factor required to convert to canonical units - basically SI with degrees and "dimensionless" additions such as byte, pixel and count.

A deprecated form of this function, wcsulex(), lacks the wcserr** parameter.

Parameters

in	unitstr	Null-terminated character array containing the units specification, with or without surrounding square brackets (for inline specifications); text following the closing bracket is ignored.				
out	func	Special function type, see note 4:				
		• 0: None				
		• 1: log()base 10				
		• 2: ln()base e				
		• 3: exp()				
out	scale	Scale factor for the unit specification; multiply a value expressed in the given units by this				
		factor to convert it to canonical units.				
out	units	A units specification is decomposed into powers of 16 fundamental unit types: angle, mass, length, time, count, pixel, etc. Preprocessor macro WCSUNITS_NTYPE is defined to dimension this vector, and others such WCSUNITS_PLANE_ANGLE, WCSUNITS_LENGTH, etc. to access its elements. Corresponding character strings, wcsunits_types[] and wcsunits_units[], are predefined to describe each quantity and its canonical units.				
out	err	If enabled, for function return values > 1, this struct will contain a detailed error message, see wcserr_enable(). May be NULL if an error message is not desired. Otherwise, the user is responsible for deleting the memory allocated for the wcserr struct.				

Returns

Status return value:

- 0: Success.
- 1: Invalid numeric multiplier.
- 2: Dangling binary operator.

- · 3: Invalid symbol in INITIAL context.
- · 4: Function in invalid context.
- 5: Invalid symbol in EXPON context.
- 6: Unbalanced bracket.
- 7: Unbalanced parenthesis.
- 8: Consecutive binary operators.
- 9: Internal parser error.

scale and units[] are zeroed on return if an error occurs.

Notes:

- wcsulexe() is permissive in accepting whitespace in all contexts in a units specification where it does not create ambiguity (e.g. not between a metric prefix and a basic unit string), including in strings like "log (m ** 2)" which is formally disallowed.
- 2. Supported extensions:
 - "angstrom" (OGIP usage) is allowed in addition to "Angstrom".
 - "ohm" (OGIP usage) is allowed in addition to "Ohm".
 - "Byte" (common usage) is allowed in addition to "byte".
- 3. Table 6 of WCS Paper I lists eleven units for which metric prefixes are allowed. However, in this implementation only prefixes greater than unity are allowed for "a" (annum), "yr" (year), "pc" (parsec), "bit", and "byte", and only prefixes less than unity are allowed for "mag" (stellar magnitude).
 - Metric prefix "P" (peta) is specifically forbidden for "a" (annum) to avoid confusion with "Pa" (Pascal, not peta-annum). Note that metric prefixes are specifically disallowed for "h" (hour) and "d" (day) so that "ph" (photons) cannot be interpreted as pico-hours, nor "cd" (candela) as centi-days.
- 4. Function types $\log()$, $\ln()$ and $\exp()$ may only occur at the start of the units specification. The scale and units[] returned for these refers to the string inside the function "argument", e.g. to "MHz" in $\log(\text{MHz})$ for which a scale of 10^6 will be returned.

wcsunits()

wcsutrn()

wcsulex()

6.37.5 Variable Documentation

wcsunits_errmsg

```
const char * wcsunits_errmsg[] [extern]
```

Status return messages.

Error messages to match the status value returned from each function.

wcsunits_types

```
const char * wcsunits_types[] [extern]
```

Names of physical quantities.

Names for physical quantities to match the units vector returned by **wcsulexe**():

- 0: plane angle

00077 *
00078 *
                                  the closing bracket is ignored.
00079 *
00080 * Returned:
00081 *
          scale,
00082 *
           offset.
00083 *
                      double* Convert units using
           power
00084 *
00085 =
                                   pow(scale*value + offset, power);
00086 *
                                 Normally offset is zero except for log() or ln() conversions, e.g. "log(MHz)" to "ln(Hz)". Likewise,
00087 *
00088 *
                                  power is normally unity except for exp() conversions, e.g. "exp(ms)" to "exp(/Hz)". Thus conversions
00089 *
00090 *
00091 *
                                  ordinarily consist of
00092 *
00093 =
                                    value *= scale;
00094 *
00095 *
           err
                      struct wcserr **
00096 *
                                  If enabled, for function return values > 1, this

00097 *
00098 *
                                  wcserr_enable(). May be NULL if an error message is
00099 *
                                  not desired. Otherwise, the user is responsible for
00100 *
                                  deleting the memory allocated for the wcserr struct.
00101 *
00102 * Function return value:
00103 *
                                 Status return value:
                      int
00104 *
                                     0: Success.
00105 *
                                   1-9: Status return from wcsulexe().
00106 *
                                    10: Non-conformant unit specifications.
00107 *
                                    11: Non-conformant functions.
00108 *
00109
                                  scale is zeroed on return if an error occurs.
00110 *
00111 *
00112 \star wcsutrne() - Translation of non-standard unit specifications
00113 * -
00114 \star wcsutrne() translates certain commonly used but non-standard unit strings,
00115 * e.g. "DEG", "MHZ", "KELVIN", that are not recognized by wcsulexe(), refer to 00116 * the notes below for a full list. Compounds are also recognized, e.g.
00117 * "JY/BEAM" and "KM/SEC/SEC". Extraneous embedded blanks are removed.
00118 *
00119 * A deprecated form of this function, wcsutrn(), lacks the wcserr** parameter.
00120 *
00121 * Given:
00122 *
                                  Although "S" is commonly used to represent seconds,
          ctrl
                      int
                                  its translation to "s" is potentially unsafe since the
standard recognizes "S" formally as Siemens, however
00123 *
00124 *
                                  rarely that may be used. The same applies to "H" for hours (Henry), and "D" for days (Debye). This
00125 *
00126 *
00127 *
                                  bit-flag controls what to do in such cases:
```

6.38 wcsunits.h 457

```
1: Translate "S" to "s".
                                    2: Translate "H" to "h".
4: Translate "D" to "d".
00129 *
00130 *
                                  Thus ctrl == 0 doesn't do any unsafe translations,
00131 *
00132 *
                                  whereas ctrl == 7 does all of them.
00133
00134 * Given and returned:
00135 *
           unitstr char []
                                 Null-terminated character array containing the units
00136
                                  specification to be translated.
00137 >
00138 *
                                  Inline units specifications in a FITS header
00139 *
                                  keycomment are also handled. If the first non-blank
                                  character in unitstr is '[' then the unit string is delimited by its matching ']'. Blanks preceding '['
00140 *
00141 *
00142 *
                                  will be stripped off, but text following the closing
00143 *
                                  bracket will be preserved without modification.
00144 *

                                       9: Internal parser error.
00260 *
00261 *
                                    scale and units[] are zeroed on return if an error
00262 *
                                    occurs.
00263 *
00264 * Notes:
           1: wcsulexe() is permissive in accepting whitespace in all contexts in a
                units specification where it does not create ambiguity (e.g. not
00266 *
               between a metric prefix and a basic unit string), including in strings like "log (m ** 2)" which is formally disallowed.
00267 *
00268 *
00269 *
00270 *
           2: Supported extensions:
                  "angstrom" (OGIP usage) is allowed in addition to "Angstrom".
"ohm" (OGIP usage) is allowed in addition to "Ohm".
00271 *
00272 *
               - "ohm"
00273 *
                             (common usage) is allowed in addition to "byte".
00274 *
00275 *
            3: Table 6 of WCS Paper I lists eleven units for which metric prefixes are
00276 *
               allowed. However, in this implementation only prefixes greater than unity are allowed for "a" (annum), "yr" (year), "pc" (parsec), "bit", and "byte", and only prefixes less than unity are allowed for "mag"
00277 *

6.39 wcsutil.h File Reference

Functions

void wcsdealloc (void *ptr)

free memory allocated by WCSLIB functions.

• void wcsutil_strcvt (int n, char c, int nt, const char src[], char dst[])

Copy character string with padding.

void wcsutil_blank_fill (int n, char c[])

Fill a character string with blanks.

void wcsutil_null_fill (int n, char c[])

Fill a character string with NULLs.

int wcsutil_all_ival (int nelem, int ival, const int iarr[])

Test if all elements an int array have a given value.

int wcsutil_all_dval (int nelem, double dval, const double darr[])

Test if all elements a double array have a given value.

• int wcsutil_all_sval (int nelem, const char *sval, const char(*sarr)[72])

Test if all elements a string array have a given value.

int wcsutil allEq (int nvec, int nelem, const double *first)

Test for equality of a particular vector element.

• int wcsutil_dblEq (int nelem, double tol, const double *arr1, const double *arr2)

Test for equality of two arrays of type double.

int wcsutil intEq (int nelem, const int *arr1, const int *arr2)

Test for equality of two arrays of type int.

• int wcsutil_strEq (int nelem, char(*arr1)[72], char(*arr2)[72])

Test for equality of two string arrays.

void wcsutil_setAll (int nvec, int nelem, double *first)

Set a particular vector element.

void wcsutil_setAli (int nvec, int nelem, int *first)

Set a particular vector element.

void wcsutil_setBit (int nelem, const int *sel, int bits, int *array)

Set bits in selected elements of an array.

char * wcsutil_fptr2str (void(*fptr)(void), char hext[19])

Translate pointer-to-function to string.

void wcsutil double2str (char *buf, const char *format, double value)

Translate double to string ignoring the locale.

• int wcsutil_str2double (const char *buf, double *value)

Translate string to a double, ignoring the locale.

• int wcsutil str2double2 (const char *buf, double *value)

Translate string to doubles, ignoring the locale.

6.39.1 Detailed Description

Simple utility functions. With the exception of wcsdealloc(), these functions are intended for **internal use only** by WCSLIB.

The internal-use functions are documented here solely as an aid to understanding the code. They are not intended for external use - the API may change without notice!

6.39.2 Function Documentation

wcsdealloc()

```
void wcsdealloc (
     void * ptr )
```

free memory allocated by WCSLIB functions.

wcsdealloc() invokes the free() system routine to free memory. Specifically, it is intended to free memory allocated (using calloc()) by certain WCSLIB functions (e.g. wcshdo(), wcsfixi(), fitshdr()), which it is the user's responsibility to deallocate.

In certain situations, for example multithreading, it may be important that this be done within the WCSLIB sharable library's runtime environment.

PLEASE NOTE: wcsdealloc() must not be used in place of the destructors for particular structs, such as wcsfree(), celfree(), etc.

Parameters

```
in, out | ptr | Address of the allocated memory.
```

Returns

wcsutil_strcvt()

```
void wcsutil_strcvt (
    int n,
    char c,
    int nt,
    const char src[],
    char dst[])
```

Copy character string with padding.

INTERNAL USE ONLY.

wcsutil_strcvt() copies one character string to another up to the specified maximum number of characters.

If the given string is null-terminated, then the NULL character copied to the returned string, and all characters following it up to the specified maximum, are replaced with the specified substitute character, either blank or NULL.

If the source string is not null-terminated and the substitute character is blank, then copy the maximum number of characters and do nothing further. However, if the substitute character is NULL, then the last character and all consecutive blank characters preceding it will be replaced with NULLs.

Used by the Fortran wrapper functions in translating C strings into Fortran CHARACTER variables and vice versa.

Parameters

in	n	Maximum number of characters to copy.		
in	С	Substitute character, either NULL or blank (anything other than NULL).		
in	nt	If true, then dst is of length n+1, with the last character always set to NULL.		
in	src	Character string to be copied. If null-terminated, then need not be of length n, otherwise it must		
		be.		
out	dst	Destination character string, which must be long enough to hold n characters. Note that this		
		string will not be null-terminated if the substitute character is blank.		

Returns

wcsutil_blank_fill()

```
void wcsutil_blank_fill (
    int n,
    char c[])
```

Fill a character string with blanks.

INTERNAL USE ONLY.

wcsutil_blank_fill() pads a character sub-string with blanks starting with the terminating NULL character (if any).

Parameters

in	n	Length of the sub-string.
in,out	С	The character sub-string, which will not be null-terminated on return.

Returns

wcsutil_null_fill()

```
void wcsutil_null_fill (
          int n,
          char c[])
```

Fill a character string with NULLs.

INTERNAL USE ONLY.

wcsutil_null_fill() strips trailing blanks from a string (or sub-string) and propagates the terminating NULL character (if any) to the end of the string.

If the string is not null-terminated, then the last character and all consecutive blank characters preceding it will be replaced with NULLs.

Mainly used in the C library to strip trailing blanks from FITS keyvalues. Also used to make character strings intelligible in the GNU debugger, which prints the rubbish following the terminating NULL character, thereby obscuring the valid part of the string.

Parameters

in	n	Number of characters.
in,out	С	The character (sub-)string.

Returns

wcsutil_all_ival()

```
int wcsutil_all_ival (
          int nelem,
          int ival,
          const int iarr[] )
```

Test if all elements an int array have a given value.

INTERNAL USE ONLY.

wcsutil_all_ival() tests whether all elements of an array of type int all have the specified value.

Parameters

in	nelem The length of the array.	
in	ival	Value to be tested.
in	iarr	Pointer to the first element of the array.

Returns

Status return value:

- 0: Not all equal.
- 1: All equal.

wcsutil_all_dval()

```
int wcsutil_all_dval (
    int nelem,
    double dval,
    const double darr[])
```

Test if all elements a double array have a given value.

INTERNAL USE ONLY.

wcsutil_all_dval() tests whether all elements of an array of type double all have the specified value.

Parameters

in	nelem The length of the array.	
in	dval	Value to be tested.
in	darr	Pointer to the first element of the array.

Returns

Status return value:

- 0: Not all equal.
- 1: All equal.

wcsutil_all_sval()

```
int wcsutil_all_sval (
          int nelem,
          const char * sval,
          const char(*) sarr[72] )
```

Test if all elements a string array have a given value.

INTERNAL USE ONLY.

wcsutil_all_sval() tests whether the elements of an array of type char (*)[72] all have the specified value.

Parameters

ir	nelem	nelem The length of the array.	
ir	sval	String to be tested.	
ir	sarr	Pointer to the first element of the array.	

Returns

Status return value:

- 0: Not all equal.
- 1: All equal.

wcsutil_allEq()

```
int wcsutil_allEq (
    int nvec,
    int nelem,
    const double * first )
```

Test for equality of a particular vector element.

INTERNAL USE ONLY.

wcsutil_allEq() tests for equality of a particular element in a set of vectors.

Parameters

in	nvec	The number of vectors.
in	nelem	The length of each vector.
in	first	Pointer to the first element to test in the array. The elements tested for equality are *first == *(first + nelem) == *(first + nelem*2) : == *(first + nelem*(nvec-1));
		The array might be dimensioned as double v[nvec][nelem];

Returns

Status return value:

- 0: Not all equal.
- 1: All equal.

wcsutil_dblEq()

Test for equality of two arrays of type double.

INTERNAL USE ONLY.

wcsutil_dblEq() tests for equality of two double-precision arrays.

Parameters

in	nelem	The number of elements in each array.
in	tol	Tolerance for comparison of the floating-point values. For example, for tol == 1e-6, all floating-point values in the arrays must be equal to the first 6 decimal places. A value of 0 implies exact equality.
in	arr1	The first array.
in	arr2	The second array

Returns

Status return value:

- 0: Not equal.
- 1: Equal.

wcsutil_intEq()

```
int wcsutil_intEq (
          int nelem,
```

```
const int * arr1,
const int * arr2 )
```

Test for equality of two arrays of type int.

INTERNAL USE ONLY.

wcsutil_intEq() tests for equality of two int arrays.

Parameters

in	nelem	The number of elements in each array.
in	arr1	The first array.
in	arr2	The second array

Returns

Status return value:

- 0: Not equal.
- 1: Equal.

wcsutil_strEq()

```
int wcsutil_strEq (
    int nelem,
    char(*) arr1[72],
    char(*) arr2[72] )
```

Test for equality of two string arrays.

INTERNAL USE ONLY.

wcsutil_strEq() tests for equality of two string arrays.

Parameters

in	nelem	The number of elements in each array.
in	arr1	The first array.
in	arr2	The second array

Returns

Status return value:

- 0: Not equal.
- 1: Equal.

wcsutil_setAll()

```
void wcsutil_setAll (
          int nvec,
```

```
int nelem,
double * first )
```

Set a particular vector element.

INTERNAL USE ONLY.

wcsutil_setAll() sets the value of a particular element in a set of vectors of type double.

Parameters

in	nvec	The number of vectors.
in	nelem	The length of each vector.
in,out	first	Pointer to the first element in the array, the value of which is used to set the others *(first + nelem) = *first; *(first + nelem*2) = *first; : *(first + nelem*(nvec-1)) = *first; The array might be dimensioned as double v[nvec][nelem];

Returns

wcsutil_setAli()

```
void wcsutil_setAli (
                int nvec,
                int nelem,
                int * first )
```

Set a particular vector element.

INTERNAL USE ONLY.

wcsutil_setAli() sets the value of a particular element in a set of vectors of type int.

Parameters

in	nvec	The number of vectors.
in	nelem	The length of each vector.
in,out	first	Pointer to the first element in the array, the value of which is used to set the others *(first + nelem) = *first; *(first + nelem*2) = *first; : *(first + nelem*(nvec-1)) = *first; The array might be dimensioned as int v[nvec][nelem];

Returns

wcsutil_setBit()

Set bits in selected elements of an array.

INTERNAL USE ONLY.

wcsutil_setBit() sets bits in selected elements of an array.

Parameters

in	nelem	Number of elements in the array.
in	sel	Address of a selection array of length nelem. May be specified as the null pointer in which case all elements are selected.
		Which case all elements are selected.
in	bits	Bit mask.
in,out	array	Address of the array of length nelem.

Returns

wcsutil_fptr2str()

Translate pointer-to-function to string.

INTERNAL USE ONLY.

wcsutil_fptr2str() translates a pointer-to-function to hexadecimal string representation for output. It is used by the various routines that print the contents of WCSLIB structs, noting that it is not strictly legal to type-pun a function pointer to void*. See http://stackoverflow.com/questions/2741683/how-to-format-a-function-point

Parameters

in	fptr	
out	hext	Null-terminated string. Should be at least 19 bytes in size to accomodate a 64-bit address (16
		bytes in hex), plus the leading "0x" and trailing \0'.

Returns

The address of hext.

wcsutil_double2str()

Translate double to string ignoring the locale.

INTERNAL USE ONLY.

wcsutil_double2str() converts a double to a string, but unlike <code>sprintf()</code> it ignores the locale and always uses a '.' as the decimal separator. Also, unless it includes an exponent, the formatted value will always have a fractional part, ".0" being appended if necessary.

Parameters

out	buf	The buffer to write the string into.
in	format	The formatting directive, such as "f". This may be any of the forms accepted by sprintf(), but should only include a formatting directive and nothing else. For "g" and "G" formats, unless it includes an exponent, the formatted value will always have a fractional part, ".0" being appended if necessary.
in	value	The value to convert to a string.

wcsutil_str2double()

Translate string to a double, ignoring the locale.

INTERNAL USE ONLY.

wcsutil_str2double() converts a string to a double, but unlike sscanf() it ignores the locale and always expects a '.' as the decimal separator.

Parameters

in	buf	The string containing the value
out	value	The double value parsed from the string.

wcsutil_str2double2()

Translate string to doubles, ignoring the locale.

INTERNAL USE ONLY.

6.40 wcsutil.h 471

wcsutil_str2double2() converts a string to a pair of doubles containing the integer and fractional parts. Unlike sscanf() it ignores the locale and always expects a '.' as the decimal separator.

Parameters

in	buf	The string containing the value
out	value	parts, parsed from the string.

6.40 wcsutil.h

         ptr
                    void*
                               Address of the allocated memory.
00055 *
00056 * Function return value:
00057 *
                    void
00058 *
00059
00060 * wcsutil_strcvt() - Copy character string with padding
00061 *
00062 * INTERNAL USE ONLY.
00063 *
00064 * wcsutil strcvt() copies one character string to another up to the specified
00065 * maximum number of characters.
00066 *
```

```
00067 \star If the given string is null-terminated, then the NULL character copied to
00068 \star the returned string, and all characters following it up to the specified
00069 \star maximum, are replaced with the specified substitute character, either blank
00070 * or NULL.
00071 *
00072 \star If the source string is not null-terminated and the substitute character is
00073 * blank, then copy the maximum number of characters and do nothing further.
00074 \star However, if the substitute character is NULL, then the last character and
00075 \star all consecutive blank characters preceding it will be replaced with NULLs.
00076 *
00077 \star Used by the Fortran wrapper functions in translating C strings into Fortran
00078 * CHARACTER variables and vice versa.
00079
00080 * Given:
00081 *
         n
                    int
                              Maximum number of characters to copy.
00082 *
                              Substitute character, either NULL or blank (anything
00083 *
          C
                    char
00084 *
                              other than NULL).
00085 *
00086 *
                    int
                              If true, then dst is of length n+1, with the last
         nt
00087 *
                              character always set to NULL.
00088 *
00089 *
         src
                    char[]
                              Character string to be copied. If null-terminated,
00090 *
                              then need not be of length n, otherwise it must be.
00091 *
00092 * Returned:
00093 *
                              Destination character string, which must be long
         dst
                    char[]
00094 *
                               enough to hold n characters. Note that this string
                               will not be null-terminated if the substitute
00095 *
00096 *
                              character is blank.
00097 *
00098 * Function return value:
00099 *
                    void
00100 *
00101 \star 00102 \star wcsutil_blank_fill() - Fill a character string with blanks
00103 *
00104 * INTERNAL USE ONLY.
00105 *
00106 \star wcsutil_blank_fill() pads a character sub-string with blanks starting with
00107 \star the terminating NULL character (if any).
00108 *
00109 * Given:
00110 *
                              Length of the sub-string.
                    int
         n
00111 *
00112 * Given and returned:
00113 * c
                              The character sub-string, which will not be
                  char[]
00114 *
                              null-terminated on return.
00115 *
00116 * Function return value:
00117 *
                    void
00118 *
00119 *
00120 \star wcsutil_null_fill() - Fill a character string with NULLs
00121 * ----
00122 * INTERNAL USE ONLY.
00124 \star wcsutil_null_fill() strips trailing blanks from a string (or sub-string) and
00125 \star propagates the terminating NULL character (if any) to the end of the string.
00126 *
00127 \star If the string is not null-terminated, then the last character and all
00128 * consecutive blank characters preceding it will be replaced with NULLs.
00130 \star Mainly used in the C library to strip trailing blanks from FITS keyvalues.
00131 \star Also used to make character strings intelligible in the GNU debugger, which
00132 \star prints the rubbish following the terminating NULL character, thereby
00133 \star obscuring the valid part of the string.
00134 *
00135 * Given:
00136 *
                    int
                              Number of characters.
         n
00137 *
00138 * Given and returned:
00139 * c
                    char[]
                              The character (sub-)string.
00140 *
00141 * Function return value:
00142 *
                    void
00143 *

                                  *(first + nelem*(nvec-1)) = *first;
00357 *
00358 *
                               The array might be dimensioned as
00359
00360 =
                                  int v[nvec][nelem];
00361 *
00362 * Function return value:
00363 *
                     void
00364 *
00365 *
00366 * wcsutil_setBit() - Set bits in selected elements of an array
00367 *
00368 * INTERNAL USE ONLY.
00369 *
00370 * wcsutil setBit() sets bits in selected elements of an array.
00371 *
00372 * Given:
00373 *
          nelem
                     int
                               Number of elements in the array.
00374 *
00375 *
          sel
                   const int*
00376 *
                               Address of a selection array of length nelem. May
00377 *
                               be specified as the null pointer in which case all
00378 *
                               elements are selected.
00379 *
00380 *
          bits
                    int
                               Bit mask.
00381 * 00382 * Given and returned:
00383 *
                               Address of the array of length nelem.
          array
                    int*
00385 * Function return value:
00386 *
00387 *
00388 *
00389 \star wcsutil_fptr2str() - Translate pointer-to-function to string
00390 *
00391 * INTERNAL USE ONLY.
00392 *
00393 \star wcsutil_fptr2str() translates a pointer-to-function to hexadecimal string
00394 \star representation for output. It is used by the various routines that print
00395 \star the contents of WCSLIB structs, noting that it is not strictly legal to 00396 \star type-pun a function pointer to void\star. See
00397 * http://stackoverflow.com/questions/2741683/how-to-format-a-function-pointer
00398 *
00399 * Given:
00400 * fptr
                    void(*)() Pointer to function.
00401 *
00402 * Returned:
00403 * hext
                     char[19] Null-terminated string. Should be at least 19 bytes
00404 *
                                in size to accomodate a 64-bit address (16 bytes in
                               hex), plus the leading "0x" and trailing ' \setminus 0'.
00405 *
00406 *
00407 * Function return value:
00408 *
                               The address of hext.
                    char *
00409 *
00410 *
00411 \star wcsutil_double2str() - Translate double to string ignoring the locale
00412 *
00413 * INTERNAL USE ONLY.
00414 *
```

```
00415 \star wcsutil_double2str() converts a double to a string, but unlike sprintf() it
00416 \star ignores the locale and always uses a ^{\prime}.^{\prime} as the decimal separator. Also,
00417 \star unless it includes an exponent, the formatted value will always have a 00418 \star fractional part, ".0" being appended if necessary.
00419 *
00420 * Returned:
00421 * buf
                      char *
                                The buffer to write the string into.
00422 *
00423 * Given:
                                The formatting directive, such as "%f". This
00424 *
          format
                      char *
00425 *
                                  may be any of the forms accepted by sprintf(), but
00426 *
                                   should only include a formatting directive and nothing else. For "\graysigma^*g" and "\graysigma^*G" formats, unless it
00427 *
00428 *
                                   includes an exponent, the formatted value will always
00429 *
                                   have a fractional part, ".0" being appended if
00430 *
                                   necessary.
00431 *
00432 *
          value
                     double
                                  The value to convert to a string.
00433 *
00434 *
00435 \star wcsutil_str2double() - Translate string to a double, ignoring the locale
00436 *
00437 * INTERNAL USE ONLY.
00438 *
00439 * wcsutil_str2double() converts a string to a double, but unlike sscanf() it
00440 \star ignores the locale and always expects a '.' as the decimal separator.
00441 *
00442 * Given:
                                The string containing the value
00443 * buf
                       char *
00444 *
00445 * Returned:
00446 *
           value
                      double * The double value parsed from the string.
00447 *
00448 *
00449 \star wcsutil_str2double2() - Translate string to doubles, ignoring the locale
00450 * -
00451 * INTERNAL USE ONLY.
00452 *
00453 \star wcsutil_str2double2() converts a string to a pair of doubles containing the
00454 \star integer and fractional parts. Unlike sscanf() it ignores the locale and 00455 \star always expects a '.' as the decimal separator.
00456 *
00457 * Given:
00458 *
                      char * The string containing the value
          buf
00459 *
00460 * Returned:
00461 * value
                      double[2] The double value, split into integer and fractional
00462 *
                                  parts, parsed from the string.
00463 *

struct wtbarr

Extraction of coordinate lookup tables from BINTABLE.

6.41.1 Detailed Description

The wtbarr struct is used by wcstab() in extracting coordinate lookup tables from a binary table extension (BINTABLE) and copying them into the tabprm structs stored in wcsprm.

6.42 wtbarr.h

00023 *====
00024 *
00025 \star WCSLIB 8.3 - C routines that implement the FITS World Coordinate System
00026 \star (WCS) standard. Refer to the README file provided with WCSLIB for an
00027 * overview of the library.
00028 *
00029 *
00030 * Summary of the wtbarr struct
00031 * -
00032 \star The wtbarr struct is used by wcstab() in extracting coordinate lookup tables
00033 \star from a binary table extension (BINTABLE) and copying them into the tabprm
00034 * structs stored in wcsprm.
00035 *
00036 *
00037 * wtbarr struct - Extraction of coordinate lookup tables from BINTABLE
00038 * -
00039 \star Function wcstab(), which is invoked automatically by wcspih(), sets up an
00040 \star array of wtbarr structs to assist in extracting coordinate lookup tables
00041 \star from a binary table extension (BINTABLE) and copying them into the tabprm
00042 \star structs stored in wcsprm. Refer to the usage notes for wcspih() and
00043 * wcstab() in wcshdr.h, and also the prologue to tab.h.
00044 *
00045 \star For C++ usage, because of a name space conflict with the wtbarr typedef
00046 * defined in CFITSIO header fitsio.h, the wtbarr struct is renamed to wtbarr_s
00047 \star by preprocessor macro substitution with scope limited to wtbarr.h itself,
00048 \star and similarly in wcs.h.
00049 *
00050 *
00051 *
            (Given) Image axis number.
00052 *
00053 *
00054 *
           (Given) wcstab array axis number for index vectors.
00055 *
00056 *
         int kind
00057 *
           (Given) Character identifying the wcstab array type:
              - c: coordinate array,
```

```
00059 *
             - i: index vector.
00060 *
00061 *
          char extnam[72]
           (Given) EXTNAME identifying the binary table extension.
00062 *
00063 *
00064 *
          int extver
           (Given) EXTVER identifying the binary table extension.
00066 *
00067 *
          int extlev
00068 *
           (Given) EXTLEV identifying the binary table extension.
00069 *
00070 *
          char ttvpe[72]
          (Given) TTYPEn identifying the column of the binary table that contains the wcstab array.
00071 *
00072 *
00073 *
         long row
00074 *
          (Given) Table row number.
00075 *
00076 *
00077 *
00078 *
           (Given) Expected dimensionality of the wcstab array.
00079 *
00080 *
          (Given) Address of the first element of an array of int of length ndim into which the wcstab array axis lengths are to be written.
00081 *
00082 *
00083 *
         double **arrayp
00085 *
           (Given) Pointer to an array of double which is to be allocated by the
00086 *
           user and into which the wcstab array is to be written.
00087 *

03708
03709 @endverbatim
03710 In this example, if an error was generated in one of the prjset() functions,
03711 wcsperr() would print an error traceback starting with wcsset(), then
03712 celset(), and finally the particular projection-setting function that 03713 generated the error. For each of them it would print the status return value,
03714 function name, source file, line number, and an error message which may be
03715 more specific and informative than the general error messages reported in the
03716 first example. For example, in response to a deliberately generated error,
03717 the @c twcs test program, which tests wcserr among other things, produces a
03718 traceback similar to this:
03719 @verbatim
03720 ERROR 5 in wcsset() at line 1564 of file wcs.c:
03721
        Invalid parameter value.
03722 ERROR 2 in celset() at line 196 of file cel.c:
03723
        Invalid projection parameters.
03724 ERROR 2 in bonset() at line 5727 of file prj.c:
03725
       Invalid parameters for Bonne's projection.
03726 @endverbatim
03727
03728 Each of the @ref structs "structs" in @ref overview "WCSLIB" includes a
03729 pointer, called @a err, to a wcserr struct. When an error occurs, a struct is
03730 allocated and error information stored in it. The wcserr pointers and the 03731 @ref memory "memory" allocated for them are managed by the routines that
03732 manage the various structs such as wcsinit() and wcsfree().
03733
03734 wcserr messaging is an opt-in system enabled via wcserr_enable(), as in the
03735 example above. If enabled, when an error occurs it is the user's
03736 responsibility to free the memory allocated for the error message using
03737 wcsfree(), celfree(), prjfree(), etc. Failure to do so before the struct goes
03738 out of scope will result in memory leaks (if execution continues beyond the
03739 error).
03740 */
